

AP Human Geography

During the first week of school, I will be collecting your study guide and index cards. You should create an index card for each vocabulary term. The term should be on one side and the definition and picture should be on the other side. Vocabulary is extremely important for the AP Test.

To complete the study guide, read Rubenstein's The Cultural Landscape. "Basic Concepts."

If you have any questions, email me at cpost@pasco.k12.fl.us.

Unit I. Geography: Its Nature and Perspectives—Basic Vocabulary and Concepts

Note: The following concepts transcend all units in AP Human Geography; they are central to all geographic thinking and analysis and could even be considered central to any definition of geography.

Basic Concepts
built landscape
cultural landscape
Density (arithmetic, physiological)
Diffusion (hearth, relocation, expansion
, hierarchical, contagious, stimulus)
Direction (absolute, relative)
Dispersion/concentration (dispersed/scattered, clustered/agglomerated)
Distance (absolute, relative)
Distribution
Environmental determinism
Location (absolute, relative, site, situation, toponym)
Pattern (linear, centralized, random)
Physical attributes (natural landscape)

Possibilism

Region (formal/uniform, functional/nodal, perceptual/vernacular)

Scale (implied degree of generalization)

Size

Spatial (of or pertaining to space on or near Earth's surface)

Spatial interaction (accessibility, connectivity, network, distance decay, friction of distance, time-space compression)

Geographic Tools

Distortion

Geographic Information System (GIS)

Global Positioning System (GPS)

Grid (North and South Poles, latitude, parallel, equator, longitude, meridian, prime meridian, international date line)

Map scale (distance on a map relative to distance on Earth)

Map types (thematic, statistical, cartogram, dot, choropleth, isoline)

Mental map

Model (a simplified abstraction of reality, structured to clarify causal relationships):

Projection

Remote sensing

Time zones

Thinking Geographically: Key Issue 1
How Do Geographers Address Where Things Are?
Rubenstein, pp. ~~6-9~~ 7-13

1. Define **map**:

2. Define **cartography**:

• **MAPS**

3. Give two examples of early mapmaking and its (unusual?) materials for the maps.

(a)

(b)

4. Who first demonstrated that the earth was round? How?

5a. Who was the first to use the term "geography."

5b. List three of his contributions in geography at that time.

(a)

(b)

(c)

6. Provide an example of developments in geography for each of the following:

Chinese	
Muslims	
Age of Discovery (16 th Century)	

7. Define **scale**:

8. What is the advantage of a map which shows only a small portion of the earth's surface – like a neighborhood - that is, a **large-scale map**?

8b. What advantage does a map which shows the entire globe, a **small-scale map**, have?

9. When geographers convert the round earth to a flat map, they use a **projection**. All projections have some distortion (only a globe has none). List the four things that typically become distorted in various projections.

- a.
- b.
- c.
- d.

10. Two important projections are the **Mercator** and the **Robinson**. Complete the table below to compare their advantages and disadvantages.

	ROBINSON	MERCATOR
Advantages		
Disadvantages		

11. With regard to the **Land Ordinance of 1785**, which became the official survey system for the United States, define the following:

a) **township**

b) **sections**

• CONTEMPORARY TOOLS

12. Geographers use a **GIS** (Geographic Information System) to store "layers" of data. Give three examples of types of data stored in a single layer.

13a. Define *remote sensing*.

13b. Remotely sensed images consist of pixels. What is the **smallest area** on the surface of the earth that can be scanned as a single pixel?

13c. List several things that geographers can map using remotely sensed data.

14. Complete the following regarding a *Global Positioning System*.

G P S	
Elements/components...	Uses/implementation...

Thinking Geographically: Key Issue 2
Why Is Each Point On Earth Unique?
Rubenstein, pp. 15-30

• **PLACE: UNIQUE LOCATION OF A FEATURE**

1. Define *toponym*:

2. Identify four ways in which places can receive names

- a)
- b)
- c)
- d)

3. Identify three reasons for which places sometimes change names

- a)
- b)
- c)

4. Define *site*:

5. List some site characteristics.

6. Complete the following sentence about *site*:

Human actions can _____ the characteristics of a site.

7. Define *situation*:

8. What role do familiar places have understanding *situation* of unfamiliar places?

9. What place is designated as 0 degrees longitude?

10. What is the name for the line drawn at 0 degrees longitude?

11a. How is a degree of longitude or latitude further subdivided?

11b. Give an example.

12. How many degrees of longitude do you need to travel across to pass through one "hour" of time (or one time zone)?

13. How many time zones are there?

14. Read the information in the green box on page 21: Where and why were standard time zones first adopted?

WHERE?

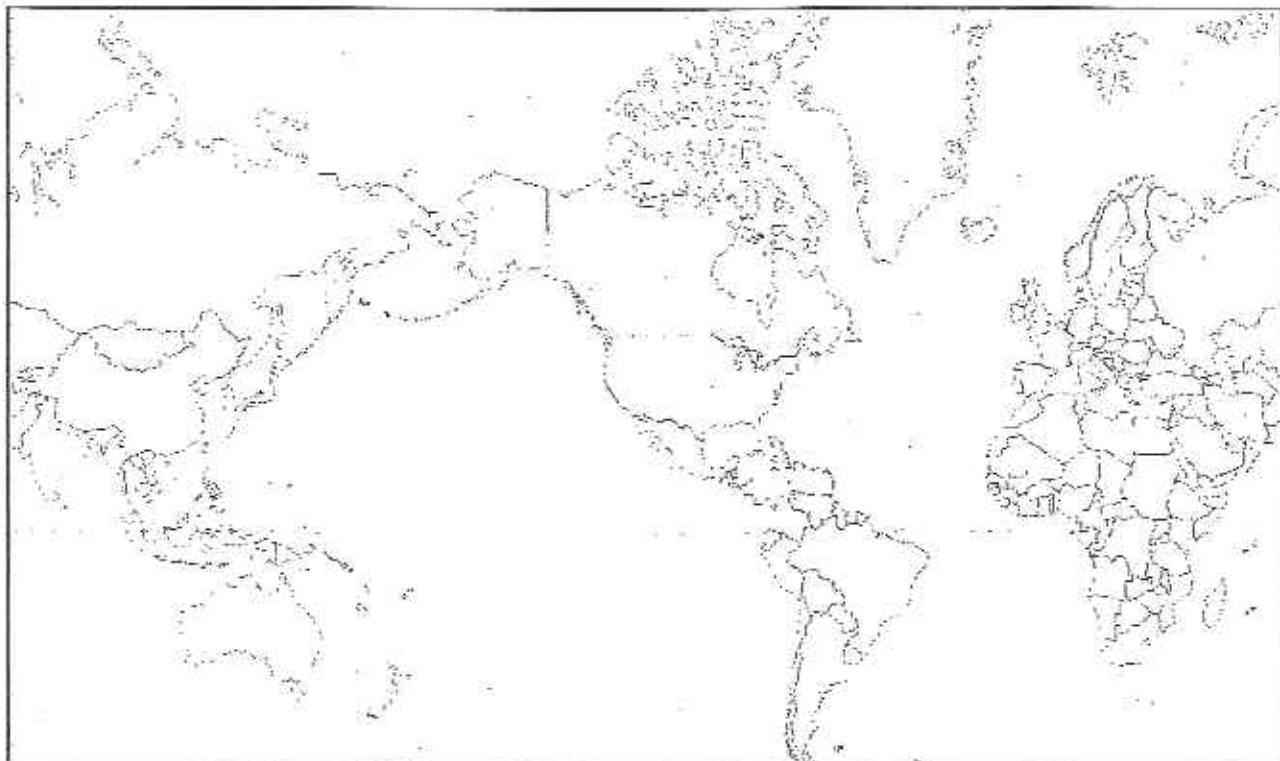

WHY?

15. What is the longitude of the International Date Line?

16. Use the map on page 19 and the green box on p. 21 to annotate the map below.

- Draw the Prime Meridian and International Date Line.
- Shade and label all countries (or regions) which use **non-standard time zones**.
- Label the country which has forced the 3000 mile **deviation** of the Prime Meridian.

• **REGIONS: AREAS OF UNIQUE CHARACTERISTICS**

16. A **region** is an _____ of _____ defined by one or more _____.

17. One contemporary (current) approach to studying the cultural landscape is called the **regional studies approach**. What do geographers who adopt this view believe regarding regions?

18. Geographers using the regional studies approach argue that that distinctive landscapes of different regions result from what two things?

- a.
- b.

19. Complete the chart below which details **types of regions** identified by geographers.

	FORMAL REGION	FUNCTIONAL REGION	VERNACULAR REGION
also called			
definition			
example			

20. How does a geographer conclude that two (or more) phenomena are "spatially associated," that is, that they bear some sort of cause and effect relationship?

21. Prepare a bullet chart about the word **CULTURE**

22. Very carefully define the following terms:

- *A. Cultural Ecology*
- *B. Environmental Determinism*
- *C. Possibilism*

23. How many major types of **climates** do geographers identify?

24. In what major way does climate influence human activities? (Give an example.)

25. List the four major **biomes**, or **major plant communities**, found naturally on earth.

- a)
- b)
- c)
- d)

26. What are the two major problems with which geographers are concerned, as far as **soil** is concerned?

- a)
- b)

27. Complete two case studies which describe human modifications of and adaptation to the local environment. To do so, annotate the blank maps and bullet in brief notes to the right of each.

A) THE NETHERLANDS

B) FLORIDA

Thinking Geographically: Key Issue 3
Why Are Different Places Similar?
Rubenstein, pp. 30-40 28-40

• SCALE: FROM LOCAL TO GLOBAL

1. Define ***globalization***:
2. How has **modern technology** played a role in globalization?
3. In what ways is globalization of culture **manifest in the landscape**?
4. In what ways has the **communications revolution** played a role in globalization?
5. Make three bulleted statements about **reactions against globalism** and globalization.
 - (a)
 - (b)
 - (c)

• SPACE: DISTRIBUTION OF FEATURES

6. The _____ of a feature in _____ is known as its ***distribution***.

7a. Define ***density***.

7b. What is ***arithmetic density***?

7c. What is ***physiological density***?

8a. The way in which a feature is spread over space is known as ***concentration***. What are the opposite ends of the spectrum of concentration?

- a.
- b.

8c. The boxes below – draw 10 dots in each so that the density is the same in each, but illustrate and label the two different kinds of concentration.

--	--

9. List the three different types of *pattern* given in the text.

- a.
- b.
- c.

10. What role does *gender* play in geography? (What is the "geography of gender")?

11. In what way do each of the following play a role in geography?

ETHNICITY	SEXUAL ORIENTATION

• CONNECTIONS BETWEEN PLACES

12. What is *space-time compression*?

13a. In the past, most interaction between places required what?

13b. How has this changed?

14. Give some examples of things that retard interaction among groups.

15. Describe the phenomenon known as *distance-decay*.

16. **Diffusion** is defined as the process by which a characteristic spreads across space. With regard to diffusion, define and, where possible, give an example of each of the following.

D I F F U S I O N	
<i>hearth</i>	
<i>relocation diffusion</i>	
<i>hierarchical diffusion</i>	
<i>contagious diffusion</i>	
<i>stimulus diffusion</i>	

Basic Concepts

What do you expect from this geography course? You may think that geography involves memorizing lists of countries and capitals or exports and imports. Perhaps you associate geography with photographic essays of exotic places in popular magazines. Contemporary geography is the scientific study of the location of people and activities across Earth and the reasons for their distribution.

Geographers ask "where" things are and "why" they are there. Historians organize material by time, because they understand that action at one point in time can result from past actions and can affect future ones. Geographers organize material by place, because they understand that something happening at one place can result from

KEY ISSUES

- 3 Why Are Different Places Similar?

Tahlie, Kellieka (Kellieka), India

local diversity. Modern communications and technology have fostered globalization, pulling people into greater cultural and economic interaction with others. All the same time, people are searching for more ways to express their unique cultural traditions and economic practices. Tensions between the simultaneous and environmental management.

As in all sciences, the study of geography requires understanding some basic concepts. For example, the definition of geography in the first paragraph included the words location and distribution. We use these words commonly in daily speech, but geographers give them precise meanings. This first chapter introduces how human geographers think about the world. As in all sciences, the study of geography requires the logical arrangement of human activities in space. The logical arrangement of human activities in time, whereas geographers study of human activities in time, whereas geographers study the logical arrangement of human activities in space. Geographers observe that people are being pulled in opposite directions by two factors—globalization and local diversity. Globalization is the process of increasing interdependence among people around the world. It is the result of technological advances in communications and transportation that have made it easier and cheaper to move goods and ideas across great distances. Globalization has led to increased trade, investment, and cultural exchange between countries. It has also created new opportunities for business and employment, but it has also led to social inequality and environmental degradation. Local diversity refers to the rich cultural heritage and unique way of life found in different parts of the world. It is often threatened by globalization, which can lead to homogenization and loss of traditional knowledge and practices. However, local diversity is also a source of strength and resilience, providing a foundation for sustainable development and social cohesion. The challenge for geographers is to understand the complex dynamics of globalization and local diversity, and to promote sustainable development that respects both.

CASE STUDY / Big Mac Attack

If when driving across the vast expanses of the United States on an interstate highway you are hit by hunger pangs, you are unlikely to be thinking about geography. At the next interchange you scan the horizon for fast-food restaurant signs, again in vain.

Now, very hungry, you are again disappointed at the second interchange. Finally, as you approach the third interchange, you spot a familiar image atop a very large pole—McDonald's "golden arches." When you drive up the ramp from the highway to the local road, you are confronted with a choice of a half-dozen fast-food restaurants. Very annoyed, you wonder why none of these establishments were located at the two previous interchanges.

Why cluster a half dozen at a single interchange instead of dispersing one or two at each interchange? Now you are asking questions about geography. Geographers ask where things are located and why.

Geographers are interested in the location of McDonald's restaurants around the world, not just around a U.S. interstate exit. The spread of McDonald's from a single establishment in Des Plaines, Illinois, in 1955, to 32,000 establishments worldwide reflects what for many human geographers was the defining trend of the late twentieth century—globalization of economy and

culture. Human geographers are interested in understanding the economic and cultural conditions that permitted, and even encouraged, companies such as McDonald's to spread around the world during that time. Especially significant for some human geographers is the prominent role played by corporations such as Coca-Cola, Toyota, and Microsoft in the creation of a global economy and culture.

In the twenty-first century, human geographers also recognize that global forces have not eliminated local diversity in economic conditions and cultural preferences. McDonald's success has been built on many individual decisions concerning the local economy and culture. The company encourages local operators to tailor menu items to local tastes—such as India's Maharaja Mac (with lamb patties) and Uruguay's McHuevo (hamburger with poached egg)—and it avoids countries where few people can afford its meals.

Human geography is an especially exciting subject in the twenty-first century because of the constant interplay between the common and the exotic, between global forces and local distinctiveness. Every McDonald's—every place on Earth—is in some way tied to a global economy and culture, yet at the same time reflects certain characteristics that are unlike anywhere else. ■■■

The word *geography*, invented by the ancient Greek scholar Eratosthenes, is based on two Greek words. *Geo* means "Earth," and *graphy* means "to write."

Thinking geographically is one of the oldest human activities. Perhaps the first geographer was a prehistoric human who crossed a river or climbed a hill, observed what was on the other side, returned home to tell about it, and scratched the route in the dirt. Perhaps the second geographer was a friend or relative who followed the dirt map to reach the other side. Today, geographers are still trying to reach the other side, to understand more about the world in which we live. Geography is the study of where things are found on Earth's surface and the reasons for the location. Human geographers ask two simple questions: Where are people and activities found on Earth? Why are they found there?

Geography is divided broadly into two categories—*human geography* and *physical geography*—and within each category, slightly different "where" and "why" questions are addressed.

- **Human geography** is the study of where and why human activities are located where they are—for example, religions, businesses, and cities.
- **Physical geography** studies where and why natural forces occur as they do—for example, climates, landforms, and types of vegetation.

This book focuses on human geography, but it never forgets Earth's atmosphere, land, water, vegetation, and other

living creatures. Relationships such as these between humans and nature will be examined throughout. The final chapter of the book will explicitly tie human activities to the physical environment.

To introduce human geography, we concentrate on two main features of human behavior—culture and economy. The first half of the book explains why the most important cultural features, such as major languages, religions, and ethnicities, are arranged as they are across Earth. The second half of the book looks at the locations of the most important economic activities, including agriculture, manufacturing, and services.

This first chapter introduces basic concepts that geographers employ to address their "where" and "why" questions. Many of these concepts are words commonly employed in English but given particular meaning by geographers. The first key issue in this chapter looks at geography's most important tool—mapping. A **map** is a two-dimensional or flat-scale model of Earth's surface, or a portion of it. Geography is immediately distinguished from other disciplines by its reliance on maps to display and analyze information (Figure 1-1).

The second and third sections of this chapter look at basic concepts geographers use to ask two principal "why" questions. First, geographers want to know why each place on Earth is in some ways unique. For example, why do people living close to each other speak different languages and employ different methods of agriculture? Geographers use two basic concepts to explain why every place is unique—place and region.

KEY ISSUE 1

Geographers Describe Where Things Are?

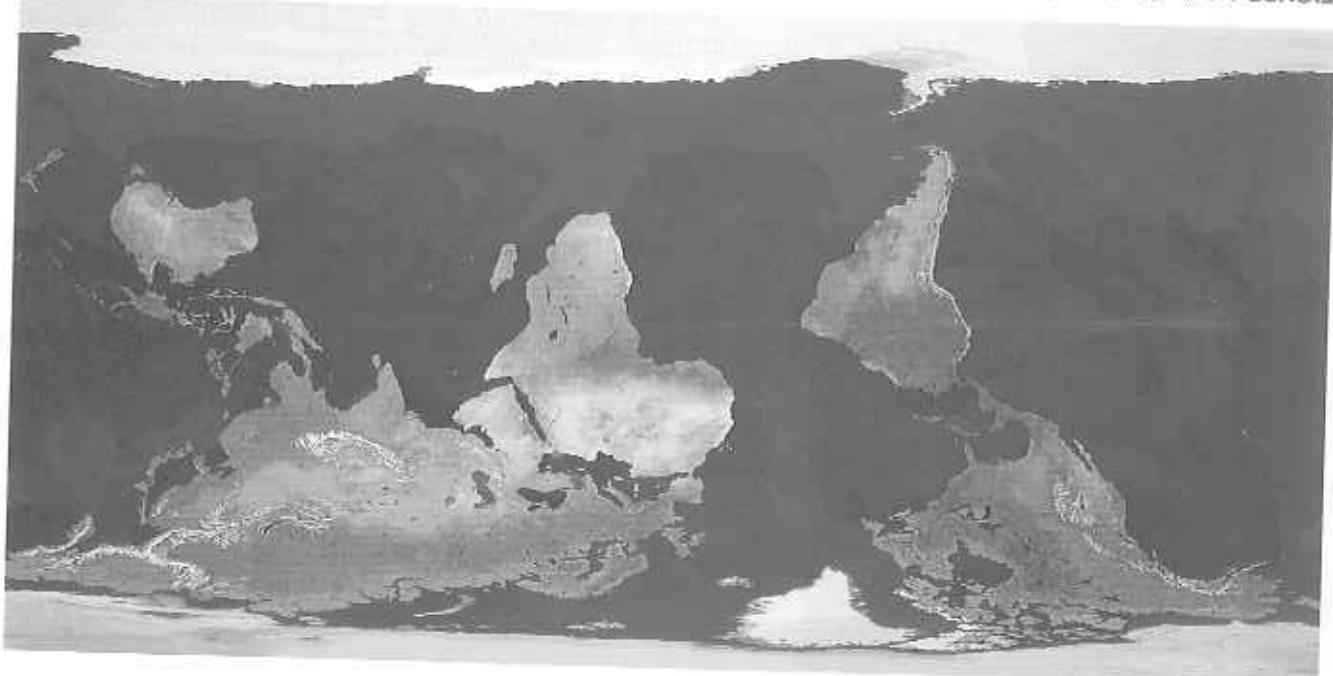

- Contemporary Tools
- Maps

Geography's most important tool for thinking spatially about the distribution of features across Earth is a map; [B]efore travel began a map existed first" (Zbigniew Herder, "Home," in *Still Life with a Bridle*).

As you turn the pages of this book, the first thing you may notice is the large number of maps—more than 200. These maps range in size from small boxes covering part of a city (Figure 2-31) to two-page spreads of the entire world (Figures 5-16 and 6-2). Some are highly detailed, with complex colors, lines, points, and shadings, whereas others seem highly generalized and unrealistic. For centuries, geographers have worked to perfect the science of mapmaking, called cartography. Contemporay cartographers are assisted by computers and satellite imagery. ■

- A place is a specific point on Earth distinguished by a particular characteristic. Every place occupies a unique location, or position, on Earth's surface, and geographers have many ways to identify location.
 - A region is an area of Earth distinguished by a distinctive combination of cultural and physical features. Human geography is concerned with the cultural features of a group of people in a region—the body of beliefs and traditions, as well as their political and economic practices.
 - The third key issue in this chapter looks at geography's other main "why" question. Geographers want to know why different places on Earth have similar features. For example, why do people living far apart from each other practice the same religion and earn a living in similar ways?
 - Three basic concepts—scale, space, and connections—help geographers explain why these similarities do not result from coincidence.
 - Scale is the relationship between the portion of Earth being studied and Earth as a whole. Although geographers study every scale from the individual to the entire Earth, they are concerned with global-scale patterns and processes.
 - Space refers to the physical gap or interval between two objects. Geographers observe that many objects are distributed across space in a regular manner, for discernible reasons.
 - Connections are relationships among people and objects across the barrier of space. Geographers are concerned with the various means by which connections occur.

FIGURE 1-1 Satellite image of the world. The composite image was assembled by the International Oceanographic Atmospheric Administration. The images were recorded over a ten-month period by satellites of the National Oceanic and Atmospheric Administration. The image like a jigsaw puzzle.

Maps

A map is a scale model of the real world, made small enough to work with on a desk or computer. It can be a hasty here's-how-to-get-to-the-party sketch, an elaborate work of art, or a precise computer-generated product. A map serves two purposes: It is a tool for storing reference material and a tool for communicating geographic information.

- **As a reference tool.** A map helps us to find the shortest route between two places and to avoid getting lost along the way. We consult maps to learn where in the world something is found, especially in relation to a place we know, such as a town, body of water, or highway. The maps in an atlas or a road map are especially useful for this purpose.
- **As a communications tool.** A map is often the best means for depicting the distribution of human activities or physical features, as well as for thinking about reasons underlying a distribution.

A series of maps of the same area over several years can reveal dynamic processes at work, such as human migration or spread of a disease. Patterns on maps may suggest interactions among different features of Earth. Placing information on a map is a principal way that geographers share data or results of scientific analysis.

Early Mapmaking

From the earliest human occupancy of Earth, people have been creating maps to assist with navigation. The earliest surviving maps were drawn in the Middle East in the seventh or sixth century BC (Figure 1-2). Miletus, a port in present-day Turkey, became a center for geographic thought and mapmaking in the ancient world. Thales (624?–546? BC) applied principles of geometry to measuring land area. His student, Anaximander (610–546? BC), made a world map based on information from sailors, though he portrayed Earth's shape as a cylinder. Hecateus may have produced the first geography book around 500 BC.

Aristotle (384–322 BC) was the first to demonstrate that Earth was spherical. He observed that matter falls together toward a common center, that Earth's shadow on the Moon is circular during an eclipse, and that the visible groups of stars change as one travels north or south.

Eratosthenes (276?–194? BC), the first person of record to use the word *geography*, also accepted that Earth was spherical and calculated its circumference within a remarkable 0.5 percent accuracy. He prepared one of the earliest maps of the known world, correctly dividing Earth into five climatic regions—a torrid zone across the middle, two frigid zones at the extreme north and south, and two temperate bands in between.

Two thousand years ago, the Roman Empire controlled an extensive area of the known world, including much of Europe, northern Africa, and western Asia. Taking advantage of information collected by merchants and soldiers who traveled through the Roman Empire, the Greek Ptolemy (AD 100?–170?) wrote an eight-volume *Guide to Geography*. He codified basic principles of mapmaking and prepared numerous maps, which were not improved upon for more than a

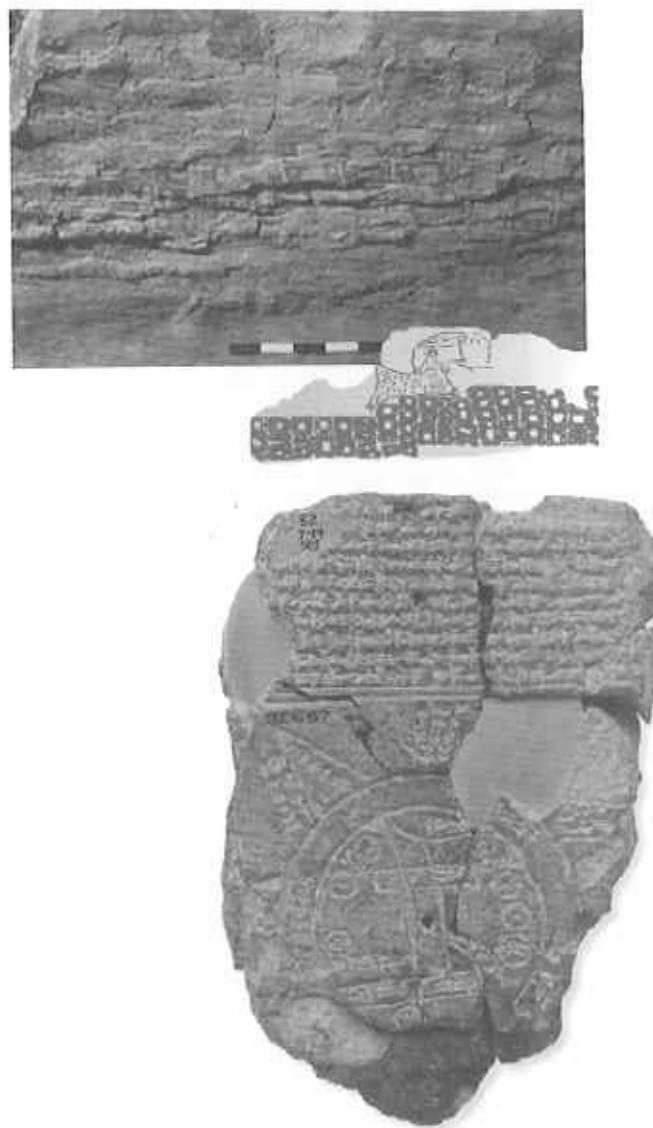

FIGURE 1-2 The oldest known maps. (top) A seventh century BC map of a plan for the town of Çatalhöyük, in present-day Turkey. Archaeologists found the map on the wall of a house that was excavated in the 1960s. (middle) A color version of the Çatalhöyük map. A volcano rises above the buildings of the city. (bottom) A world map from the sixth century BC depicts a circular land area surrounded by a ring of water. The ancient city of Babylon is thought to be shown in the center of the land area and other cities are shown as circles. Extending out from the water ring are seven islands that together form a star shape.

thousand years. Ancient Greek and Roman maps were compiled in the *Barrington Atlas of the Greek and Roman World*. “We can't truly understand the Greeks and Romans without good maps that show us their world,” explained *Barrington Atlas* editor Richard J. A. Talbert.

After Ptolemy, little progress in mapmaking or geographic thought was made in Europe for several hundred years. Maps became less mathematical and more fanciful, showing Earth as a flat disk surrounded by fierce animals and monsters. Geographic inquiry continued, though, outside of Europe.

- A model of the entire world, many details must be omitted because there simply is not enough space. Conversely, if a map shows only a small portion of Earth's surface, such as a street map of a city, it can provide a wealth of detail about a particular place.
 - The level of detail and the amount of area covered on a map depends on its scale. When specifically applied to a map, scale refers to the relationship of a feature's size on a map to its actual size on Earth. Map scale is presented in three ways (Figure 1-4).
 - A ratio or fraction shows the mathematical ratio between distances on the map and Earth's surface. A scale of 1:24,000 or 1/24,000 means that 1 unit (inch, centimeter, foot, finger length) on the map represents 24,000 of the same unit (inch, centimeter, foot, finger length) on the ground. The scale unit (inch, centimeter, foot, finger length) on the map is called a scale bar.
 - A ratio or fraction shows the mathematical ratio between distances on the map and Earth's surface. A scale of 1:24,000 or 1/24,000 means that 1 unit (inch, centimeter, foot, finger length) on the map represents 24,000 of the same unit (inch, centimeter, foot, finger length) on the ground. The scale unit (inch, centimeter, foot, finger length) on the map is called a scale bar.
 - A written scale describes the distance between map and Earth distances in words. For example, the statement "1 mile equals 1 mile" on a map means that 1 inch on the map represents 1 mile on Earth's surface. Again, the first number always refers to map distance, and the second to distance on Earth's surface.
 - A graphic scale consists of a bar line marked to show distance on Earth's surface. First determine with a ruler the distance on the map in inches or centimeters. Then hold the ruler against the bar line and read the number on the bar line to find the map distance in miles.

The first destination a cartographer faces is how much of Earth's surface to depict on the map. Is it necessary to show the entire globe, or just one continent, or a country, or a city? To make a scale

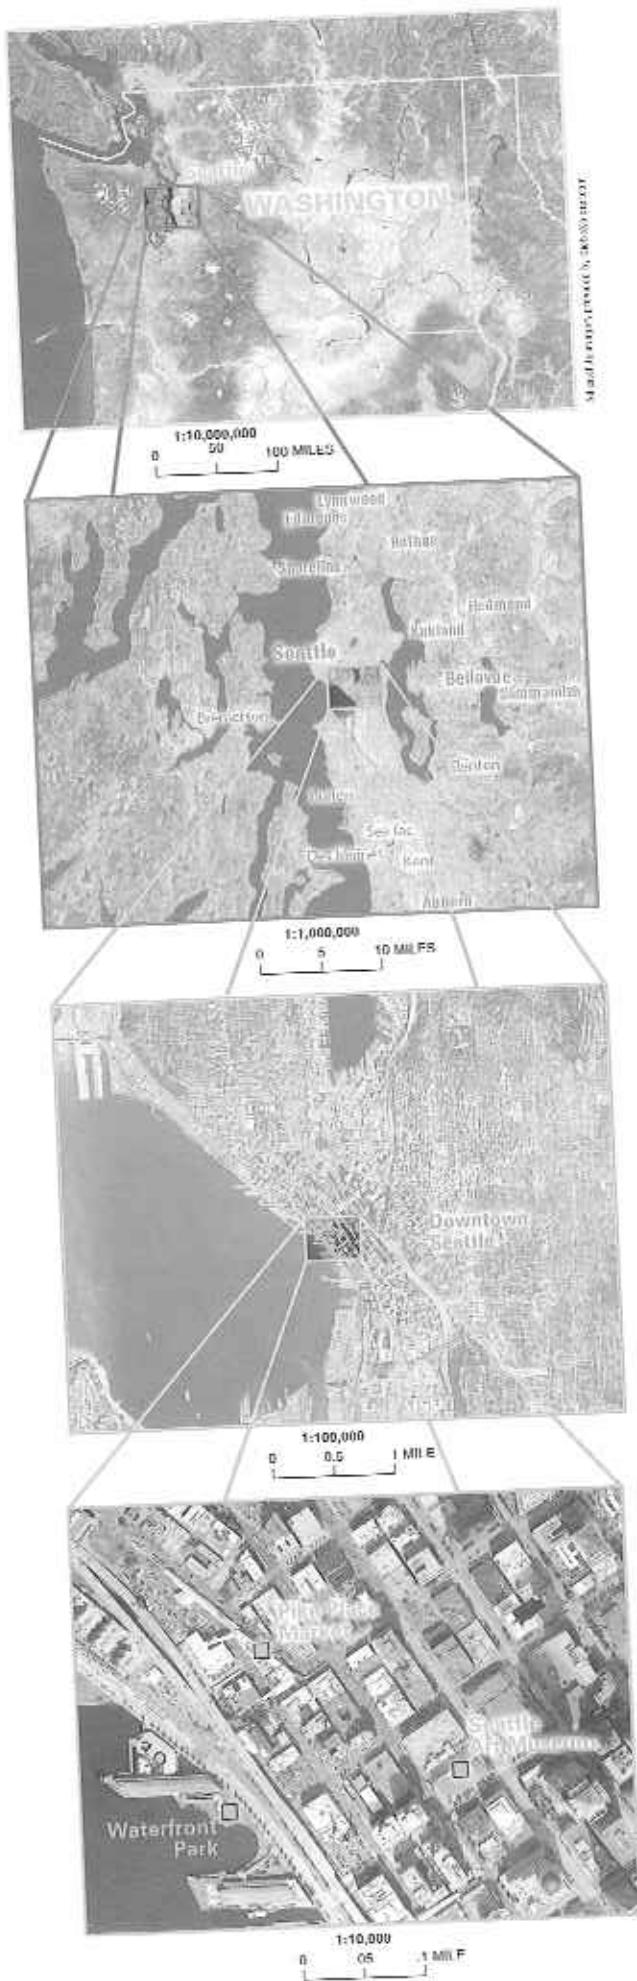

Map Scale

A revival of geography and mapmaking occurred during the Age of Exploration and Discovery. Ptolemy's maps were rediscovered, and his writings were translated into English. Columbus, Magellan, and other explorers who sailed across the oceans in search of trade routes and resources required accurate maps to reach desired destinations without wrecking their ships. In turn, cartographers such as Gerardus Mercator (1512–1594) and Abraham Ortelius (1527–1598) took information collected by the explorers to create more accurate maps (Figure 1-3).

- The oldest Chinese geographical writing, from the fifth century BC, describes the economic resources of the country's different provinces. Phet Hsü (or Fei Xu), the "father of Chinese cartography", produced an elaborate map of the world map and geography next to it 1154, building on Ptolemy's long-neglected work. Lin-Batuan (1304-1368?) wrote *Rihah* ("Travels"), based on three decades of journeys through more than 120,000 kilometers (75,000 miles) of China and much of Asia.

FIGURE 1-3 Map of the world made in 1571 by Flemish cartographer Abraham Ortelius (1527-1598). Compare the accuracy of the coastlines shown on Ortelius' map with the recent images of the world based on satellite photography (Figure 1-1).

The appropriate scale for a map depends on the information being portrayed. A map of a downtown area, such as Figure 1-4 bottom, has a scale of 1:10,000, whereas the map of Washington State (Figure 1-4 top) has a scale of 1:10,000,000. One inch represents about 1/6 mile on the downtown Seattle map and about 170 miles on the Washington State map.

At the scale of a small portion of Earth's surface, such as a downtown area, a map provides a wealth of details about the place. At the scale of the entire globe, a map must omit many details because of lack of space, but it can effectively communicate processes and trends that affect everyone.

Projection

Earth is very nearly a sphere and therefore accurately represented in the form of a globe. However, a globe is an extremely limited tool with which to communicate information about Earth's surface. A small globe does not have enough space to display detailed information, whereas a large globe is too bulky and cumbersome to use. And a globe is difficult to write on, photocopy, display on a computer screen, or carry in the glove box of a car. Consequently, most maps—including those in this book—are flat. Three-dimensional maps can be made but are expensive and difficult to reproduce.

Earth's spherical shape poses a challenge for cartographers because drawing Earth on a flat piece of paper unavoidably produces some distortion. Cartographers have invented hundreds of clever methods of producing flat maps, but none has produced perfect results. The scientific method of transferring locations on Earth's surface to a flat map is called **projection**.

The problem of distortion is especially severe for maps depicting the entire world. Four types of distortion can result:

1. The **shape** of an area can be distorted, so that it appears more elongated or squat than in reality.
2. The **distance** between two points may become increased or decreased.
3. The **relative size** of different areas may be altered, so that one area may appear larger than another on a map but is in reality smaller.
4. The **direction** from one place to another can be distorted.

Most of the world maps in this book, such as Figure 1-19, are *equal area projections*. The primary benefit of this type of projection is that the relative sizes of the landmasses on the map are the same as in reality. The projection minimizes distortion in the shapes of most landmasses. Areas toward the North and South poles—such as Greenland and Australia—become more distorted, but they are sparsely inhabited, so distorting their shapes usually is not important.

FIGURE 1-4 Map scale. The four images show Washington State (first), western Washington (second), the Seattle region (third), and downtown Seattle (fourth). The map of Washington State has a fractional scale of 1:10,000,000. Expressed as a written statement, 1 inch on the map represents 10 million inches (about 158 miles) on the ground. Look what happens to the scale on the other three maps. As the area covered gets smaller, the maps get more detailed, and 1 inch on the map represents smaller distances.

REMOTE SENSING. The acquisition of data about Earth's surface from a satellite orbiting Earth or from other long-distance methods is known as **remote sensing**. Remote sensing satellites transmit data in digital form to a receiving station on Earth.

GPS devices enable private individuals to contribute to the production of accurate digital maps, through web sites like Google's OpenStreetMap.org. Travellers can enter information about streets, buildings, and bodies of water in their GPSes to help the precise location of objects collected in fieldwork. That information can later be entered as a layer in a GIS.

GPSes can also be used to find the precise location of a destination, and GPS provides instructions on how to reach the vehicle, enabling a motorist to summon help in an emergency situation. GPSes are commonly used for navigation. Pilots of aircraft and ships stay on course with GPS. On land, GPS detects a vehicle's current position, the motorist programs the desired destination, and GPS provides instructions on how to reach the vehicle.

- A receiver that can locate at least 4 satellites, figure out the distance to each, and use this information to pinpoint its own location.
- Tracking stations to monitor and control the satellites
- Satellites placed in predetermined orbits by the U.S. military (24 in operation and 3 in reserve)

GPS. The system that accurately determines the precise position of something on Earth is **GPS (Global Positioning System)**. The GPS system in the United States includes three elements:

GPS satellites are orbiting around Earth to record information to receive signals from satellites in orbit above Earth and send them back to ground stations. These stations then calculate the precise location of each satellite based on the time it took for the signal to travel from the satellite to the station. This information is then sent to a central computer system, which uses complex algorithms to determine the precise location of each satellite.

Satellite-based imagery

Having largely completed the formidable task of accurately mapping Earth's surface, which required several centuries, mapmakers have turned to Geographic Information Science (GIScience) to learn more about places. GIScience helps geographers interpret information to electronically devices on Earth to record and interpret information to receive signals from satellites in orbit above Earth about that place.

Having largely completed the formidable task of accurately

Contemporary Tools

The township and section system remains important in the Midwest, farm fields in Iowa, and major streets in Chicago. Midwest states, like Illinois, the location of highways across the United States. It explains the location of objects across the nation. Understanding the location of objects across the country is fundamental to Geographic Information Science.

The township and section system of Section 32, roughly as a homestead. The Tallahatchie River is located in the southwest and southern quadrants of Section 32.

or 160 acres, was the amount of land many Western pioneers

transmitted in digital form to a receiving station on Earth. Images in the thin lines you can see on a TV screen, images are transmitted as the northeast, northwest, southwest, and southeast quarters of a particular section. A quarter-section, which is 0.25 mile by 0.25 mile, is divided into four quadrants, each of which is 1 mile by 1 mile (Figure 1-5, lower left). Sections are numbered in a consistent order, from 1 in the northeast to 36 in the south in a clockwise order. A township is divided into 36 sections, each of which is 1 mile along 90° west longitude.

A township has a second number, known as the range, that runs east-west across Mississippi and east of a principal meridian. For example, is in Township 72N R1E, north of a base line that are designated R1E (Range 1 East). The Tallahatchie River, for instance, lowwashes in the first column east of a principal meridian, corresponding to its location east of a principal meridian T1S, and so on.

The second row to the north is T2N, the first row to the south is T2S, and so on. The second row of a base line is called T1N (Township 1 North), the first row of a base line is called T1S (Township 1 South).

Each township has a number corresponding to its distance from north or south of a particular base line. Lowwashes in the first base lines (Figure 1-5, upper left).

Some of the north-south lines separating townships are called principal meridians, and some east-west lines are called principal meridians.

In this system, a township is a square 6 miles on each side, divided into the Surveyor General. Townships were first surveyed in 1789, responsibility for surveying was transferred to the United States in 1781. After the initial surveying was performed by Thomas Hutchins, who and ranges to facilitate the sale of land to settlers in the West. 1785 divided much of the country into a system of townships of the world. In the United States, the Land Ordinance of 1785 established midpoints of locations are used in different parts of the globe and longitude, other than to the global system of latitude and longitude.

U.S. Land Ordinance of 1785

Compares the sizes of Greatland and South America in the maps shown in Figures 1-13 and 1-19. The map in Figure 1-19 illustrates their size accurately.

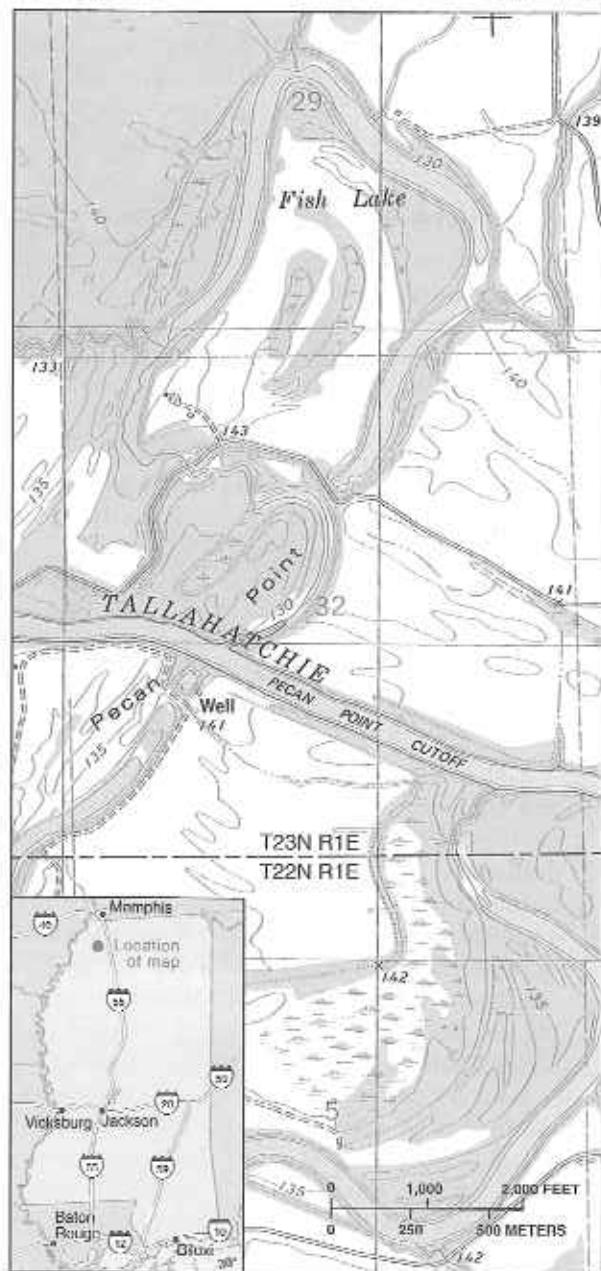

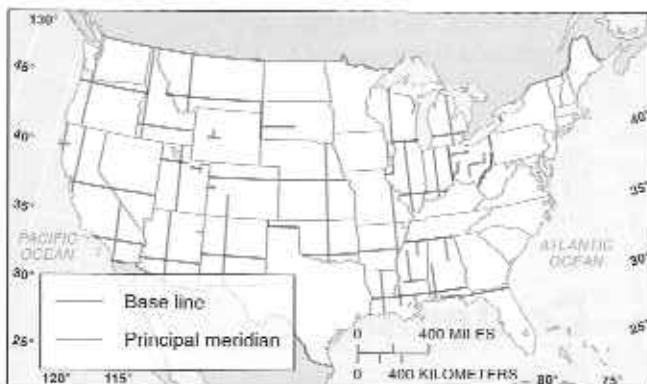

The Mercator projection in Figure 1-13 has several advantages and the map is rectangular. Its greatest disadvantage is that shape is distorted very little, direction is consistent, and ranges look much larger than they actually are.

The Robinson projection in Figure 1-23, is useful for displaying large areas by allocating space to the oceans. Its major disadvantage is that shape is distorted very little, direction is consistent, playing major role across the oceans. Its major disadvantage is that by allocating space to the oceans, the land areas are much smaller than on interrupted maps of the same size.

Two types of interrupted projections display information as shown in Figure 1-13 and 1-23 on pages 18 and 30.

The Mercator, a characteristic known as interruption, two pieces, a characteristically known as interruption. The Eastern and Western hemispheres are separated into quadrilaterals (the horizontal lines). The vertical lines are all merged at the North and South poles, do not converge at all on the map. Also, they do not form right angles with the vertical lines (the vertical lines), which is really common in the pieces, a characteristically known as interruption.

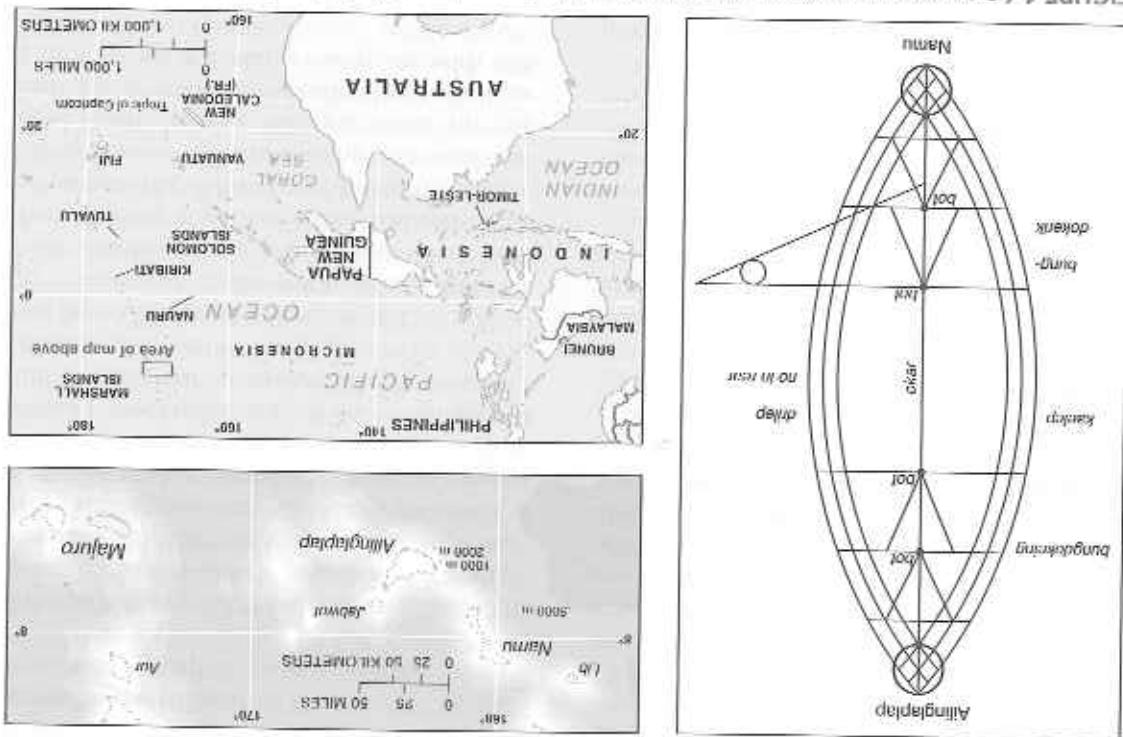

To largely preserve the size and shape of landmasses, however, the projection in Figure 1-19 forces other distortions;

FIGURE 1-5 Township and range system. To facilitate the numbering of townships, the U.S. Land Ordinance of 1785 designated several north-south lines as principal meridians and several east-west lines as base lines (upper left). As territory farther west was settled, additional lines were delineated. Townships are typically 6 miles by 6 miles, although physical features, such as rivers and mountains, result in some irregularly shaped ones (upper right). The Tallahatchie River, for example, is located in the twenty third township north of a base line that runs east-west across Mississippi and in the first range east of the principal meridian at 90° west longitude. Townships are divided into 36 sections, each 1 square mile. Sections are divided into four quarter-sections. The Tallahatchie River is located in the southeast and southwest quarter sections of Section 32, T23N R1E. The topographic map (lower left), published by the U.S. Geological Survey, has a fractional scale of 1:24,000. Expressed as a written statement, 1 inch on the map represents 24,000 inches (2,000 feet) on the ground. The map displays portions of two townships, shown on the above map. The brown lines on the map are contour lines that show the elevation of any location.

FIGURE 1-B ROLY-POLY ISLAND, STICK CAY, A TYPE OF SALT-TRAP MAP. Islands were shown with shells, and patterns of swelling of waves were shown with palm fronds. Curved stripes and straight stripes made of palm represent different wave swells. This ancient example depicted the sea route between Anguilla and Nauru, two islands in the present-day Marshall Islands, in the South Pacific Ocean. The top of the stick chart faces southward.

Two companies are responsible for supplying most of the information fed into navigation devices: Navicx, short for Navigation Technologies, and Tele Atlas, originally known as Tekk. Navicx, based in the United States, and Tele Atlas, based in the Netherlands and Belgium, both were founded in 1985. Navicx and Tele Atlas get their information from what they call "ground truthing." Hundreds of field researchers drive around, building databases of road networks. One person drives while other feeds information into a notebook computer. Hundreds of alterations are recorded such as crosswalks, turn restrictions, and name changes. Thus, electronic navigation systems ultimately depend on human observation.

Crosswalks, traffic lights, and turn restrictive conditions. Current technology does not incorporate every possible alternative, such as portable construction, weather, and time of day, but presumably, future models will.

Most trips involve making a choice from among alternative routes. Navigation devices calculate which route will get you from Point A to Point B in the fastest time. Time is a function of a combination of speed and distance. The shortest route may not always be the easiest road, such as the presence of higher expected speed than a local road.

Navigation Devices from Hand-Drawn to Electronic CONTEMPORARY GEOGRAPHIC TOOLS

At any moment a satellite sensor records the image of a tiny area called a picture element or pixel. Scanners are detecting the radiation being reflected from that tiny area. A map created by remote sensing is essentially a grid containing many rows of pixels. The resolution of the scanner determines the smallest feature on Earth's surface that can be detected by a sensor. Some can sense objects as small as 1 meter across.

GIS

A computer system that can capture, store, query, analyze, and display geographic data is a **GIS (geographic information system)**. The key to GIS is geocoding: The position of any object on Earth can be measured and recorded with mathematical precision and then stored in a computer.

GIS can be used to produce maps (including those in this book) that are more accurate and attractive than those drawn by hand. A map can be created by asking the computer to retrieve a number of stored objects and combine them to form an image. In the past, when cartographers drew maps with pen and paper, a careless moment could result in an object being placed in the wrong location, and a slip of the hand could ruin hours of work. GIS is more efficient for making a map than pen and ink: Objects can be added or removed, colors brightened or toned down, and mistakes corrected (as long as humans find them!) without having to tear up the paper and start from scratch.

Each type of information can be stored in a layer. For example, separate layers could be created for boundaries of countries, bodies of water, roads, and names of places. A simple map might display only a single layer by itself, but most maps combine several layers (Figure 1-7), and GIS permits construction of much more complex maps than can be drawn by hand.

The value of GIS extends beyond the ability to make complex maps more easily. Layers can be compared to show relationships among different kinds of information. To understand the impact of farming practices on water pollution, a physical geographer may wish to compare a layer of vegetation with a layer of bodies of water. To protect hillsides from development, a human geographer may wish to compare a layer of recently built houses with a layer of steep slopes.

Scottish environmentalist Ian McHarg pioneered a technique of comparing layers of various physical and social features to determine where new roads and houses should be built and where the landscape should be protected from development. When McHarg was developing the technique during the 1960s—before the diffusion of powerful microcomputers and GIS software—he painstakingly created layers by laying hand-drawn plastic transparencies on top of each other. A half-century later, his pioneering technique can be replicated quickly on a desktop computer with GIS software.

GIS enables geographers to calculate whether relationships between objects on a map are significant or merely coincidental. For example, maps showing where cancer rates are relatively high and low (such as those in Figure 1-17) can be

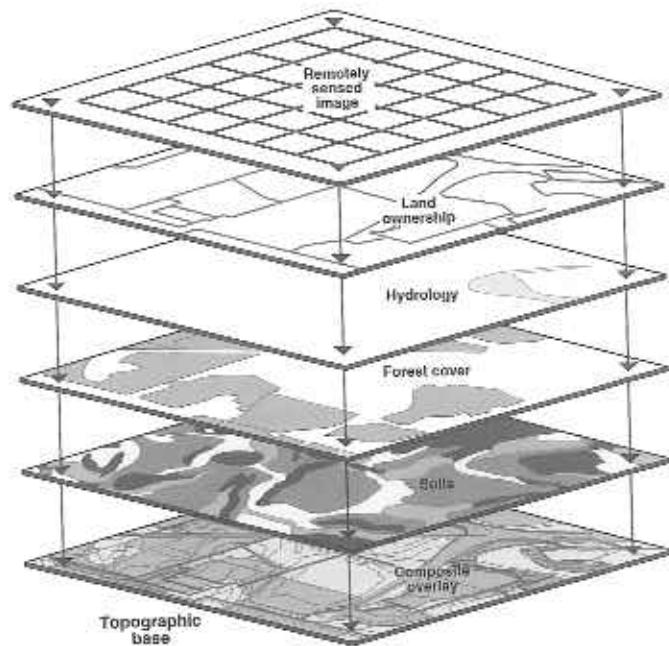

FIGURE 1-7 GIS. Geographic information systems involve storing information about a location in layers. Each layer represents a different piece of human or environmental information. The layers can be viewed individually or in combination.

combined with layers showing the location of people with various incomes and ethnicities, the location of different types of factories, and the location of mountains and valleys. Desktop computer users have the ability to do their own GIS because computer mapping services provide access to the application programming interface (API), which is the language that links a database such as an address list with software such as mapping. The API for mapping software available at such sites as www.google.com/apis/maps, enable a computer programmer to create a mash-up that places data on a map.

The term *mash-up* refers to the practice of overlaying data from one source on top of one of the mapping services and comes from the hip-hop practice of mixing two or more songs. Mash-up maps can show the locations of businesses and activities near a particular street or within a neighborhood in a city. The requested information could be all restaurants within 1/4 mile of an address or, to be even more specific, all pizza parlors. Mapping software can show the precise location of commercial airplanes currently in the air, the gas stations with the cheapest prices, and current traffic tie-ups on highways and bridges (Figure 1-8).

In some cities, mash-ups assist in finding housing. They pinpoint the location of houses currently for sale and apartments currently for rent. A map showing the prices of recently sold houses in the area can help a potential buyer determine how much to offer. A map showing the locations of crime in the city can help the buyer determine the safety of

Place: Unique of a Feature

—which possesses a strong sense of place—unit is, a setting for the features that contribute to the distinctiveness of a particular spot on Earth, perhaps a hometown, vacation destination, or part of a

A difference between the two concepts is partly a matter of place: a point, whereas a region is an area.

Two basic concepts help geographers to explain why every point on Earth is in some ways unique—place and region. The difference between the two concepts is partly a matter of scale:

Why things are found where they are. ■

Each place on Earth is in some respects unique and in other respects similar to other places. The interplay between the uniqueness of each place and the similarities among places lies at the heart of geographic inquiry into

- Place: Unique location of a Feature

Why Is Each Point on Earth Unique?

KEY ISSUE 2

surrounding area. Bars, hotels, sports facilities, transit stops, and other information about the neighbourhood can be mapped.

Some place names derive from features of the physical environment. Trees, valleys, bodies of water, and older natural features appear in the place names of most languages. The capital of the Netherlands, called "s-Gravenhage" in Dutch (in English, "The Hague"), means "the prince's forest". Abergavenny, in Wales, means "mouth of the River Ystwyth". Aberystwyth, in Cymyswyth, which means "valley of the Ystwyth". The name of the river, Ystwyth, in turn, is the Welsh word for "meandering", describing a stream that bends like a snake.

Pioneers lured to die American West by the prospect of land-hung gold or silver placed many picturesque names on the landscape. Place names in Nevada selected by successive miners include Lureka, Lucky Boy Pass, Gold Point, and Silver Peak. Unsuccessful Nevada pioneers sadly or bitterly named older places, such as Battle Mountain, Disaster Peak, and Massacre Lake. The name Jackpot was given in 1859 by the Elko, Nevada, country commissioners to a town near the Idaho border in recognition of the importance of legalized gambling to the local economy.

Some settlers select place names associated with religion, such as St. Louis and St. Paul, whereas older names derive from ancient history, such as Athens, Alitica, and Rome. A place commonly have British origins in North America and Australia, particularly those in Britain, Spain and elsewhere in Latin America, and Dutch origins in South Africa.

A place may be named for a person, perhaps his founder or a famous person with no connection to the community. George Washington's name has been selected for one state, and dozens of cities, including the national capital. Places may be named for an obscure person, such as Jenkinson. West Virginia, named for a mine operator, and Cassaway West Virginia, named for a mine operator.

Because all uninhabited places on Earth's surface—and many uninhabited places—have been named, the most straightforward way to describe a particular location is often by referring to its place name. A **toponym** is the name given to a place on Earth (Figure 1-9).

Place Names

Geographers describe a feature's place on Earth by identifying its location, the position that something occupies on Earth's surface, and in doing so consider four ways to identify location: place name, site, situation, and mathematical location.

country. Describing the features of a place or region is an essential building block for geography. To explain similarities, differences, and changes across Earth, geographers think about where particular places and regions are located and the combination of features that make each place and region distinctive.

FIGURE 1-6 Bus-stop, curbside, transhipment, and bus-stop locations of buses and bus stops during three routes. Rolling the mouse over a bus stop shows where the next three buses are expected.

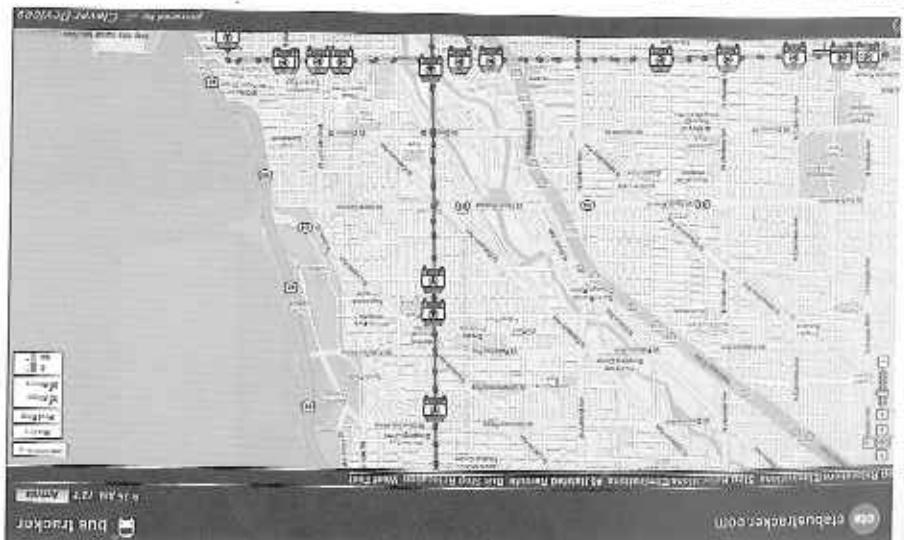

FIGURE 1-9 Welsh toponym. The town's name originally was Llanfairpwllgwyngyll, but when the railway was built in the nineteenth century, the townspeople lengthened it. They decided that signs with the 58-letter name in the railway station would attract attention and bring more business and visitors to the town.

Places can change names. The city of Cincinnati was originally named Losantiville. The name was derived as follows: *l* is for Licking River; *os* is Latin for mouth; *anti* is Latin for opposite; *ville* is Latin for town—hence, “town opposite the mouth of the Licking River.” The name was changed to Cincinnati in honor of a society of Revolutionary War heroes named after Cincinnatus, an ancient Roman general.

Hoot Springs, New Mexico, was renamed Truth or Consequences in 1950 in honor of a long-running radio and television program of that name. The name was changed by an overwhelmingly favorable vote of the residents in order to promote publicity for the economically struggling town.

The Board of Geographical Names, operated by the U.S. Geological Survey, was established in the late nineteenth century to be the final arbiter of names on U.S. maps. In recent years the board has been especially concerned with removing offensive place names, such as those with racial or ethnic connotations.

Names can also change as a result of political upheavals. For example, following World War II, Poland gained control over territory that was formerly part of Germany and changed many of the place names from German to Polish. Among the larger cities, Danzig became Gdańsk, Breslau became Wrocław, and Stettin became Szczecin. After the fall of communism in the early 1990s, names throughout Eastern Europe were changed, in many cases reverting to those used before the Communists had gained power some decades earlier. For example after the demise of communism, Gottwaldov (named for a Communist president of Czechoslovakia) reverted to its former name, Zlín, in the

Czech Republic; Leningrad (the second-largest city in the Soviet Union) reverted to St. Petersburg, Russia; and Karl-Marx-Stadt (in East Germany) reverted to Chemnitz in a reunified Germany.

Site

The second way that geographers describe the location of a place is by **site**, which is the physical character of a place. Important site characteristics include climate, water sources, topography, soil, vegetation, latitude, and elevation. The combination of physical features gives each place a distinctive character.

Site factors have always been essential in selecting locations for settlements although people have disagreed on the attributes of a good site, depending on cultural values. Some have preferred a hilltop site for easy defense from attack. Others located settlements near convenient river-crossing points to facilitate communication with people in other places.

Humans have the ability to modify the characteristics of a site. The southern portion of New York City's Manhattan Island is twice as large today as it

was in 1626, when Peter Minuit bought the island from its native inhabitants for the equivalent of \$23.75 worth of Dutch gold and silver coins (Figure 1-10). Manhattan's additional land area was created by filling in portions of the East River and the Hudson River. In the eighteenth century, landfills were created by sinking old ships and dumping refuse on top of them. More recently, New York City permitted construction of Battery Park City, a 57-hectare (142-acre) site designed to house more than 20,000 residents and 30,000 office workers. The central areas of Boston and Tokyo have also been expanded through centuries of landfilling in nearby bays, substantially changing these sites.

Situation

Situation is the location of a place relative to other places. Situation is a valuable way to indicate location, for two reasons—finding an unfamiliar place and understanding its importance.

First, situation helps us find an unfamiliar place by comparing its location with a familiar one. We give directions to people by referring to the situation of a place: “It’s down past the courthouse, on Locust Street, after the third traffic light, beside the yellow-brick bank.” We identify important buildings, streets, and other landmarks to direct people to the desired location.

Second, situation helps us understand the importance of location. Many locations are important because they are accessible to other places. For example, because of its situation, Singapore has become a center for the trading and

The meridian that passes through the Royal Observatory at Greenwich, England, is 0° longitude; also called the prime meridian. The meridian on the opposite side of the globe from the prime meridian is 180° longitude. All other meridians have numbers between 0° and 180° . East or west, depending on whether they are east or west of the prime meridian. For example, New York City is located at 74° west longitude, and Lahore, Pakistan, at 74° east longitude. San Diego is located at 117° west longitude, and Lhasa, China, at 117° east longitude.

A meridian is an arc drawn between the North and South poles. The location of each meridian is defined on Earth's surface according to a numbering system known as longitude.

The location of any place on Earth's surface can be described precisely by meridians and parallels, two sets of imaginary arcs drawn in a grid pattern on Earth's surface (Figure 1-12).

Mathematical Location

distribution of goods for much of Southeast Asia (Figure 1-1).

New York City's Manhattan Island was built on landfills. Several times in the past 200 years, the waterfront has been extended into the Hudson and East rivers to provide more land for offices, parks, warehouses and docks. The World Trade Center was built on landfills, piers, wharves and Leis drivers to accommodate more land for offices, homes, parks, warehouses and docks. The Hudson River built during the late 1960s and early 1970s partially on landfill in the Hudson River from this second era. Recently Park City (as it is left in the photograph) was built on landfill removed from the World Trade Center site in the early 1990s.

Chapter 1: Basic Concepts

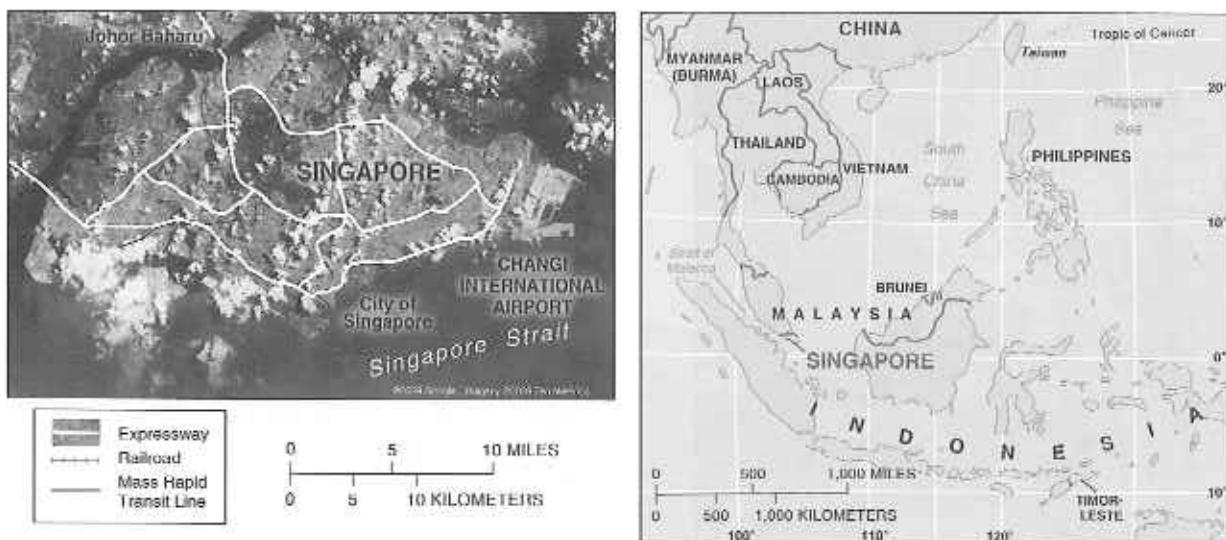

FIGURE 1-11 Situation and site of Singapore. The site of the country of Singapore is a small island approximately 1 kilometer off the southern tip of the Malay Peninsula at the eastern end of the Strait of Malacca. The city of Singapore covers nearly 20 percent of the island. Its situation is the confluence of several straits that serve as major passageways for shipping between the South China Sea and the Indian Ocean. Downtown Singapore is situated near where the Singapore River flows into the Singapore Strait.

shape and its rotation around the Sun. The equator (0° latitude) is the parallel with the largest circumference and is the place where every day has 12 hours of daylight. Even in ancient times, latitude could be accurately measured by the length of daylight and the position of the Sun and stars.

On the other hand, 0° longitude is a human creation. Any meridian could have been selected as 0° longitude, because all have the same length and all run between the poles. The 0° longitude runs through Greenwich because England was

the world's most powerful country when longitude was first accurately measured and the international agreement was made. For many centuries, inability to measure longitude was the greatest obstacle to exploration and discovery. Ships ran aground or were lost at sea because no one on board could pinpoint longitude. In 1714, the British Parliament enacted the Longitude Act, which offered a prize equivalent to several million in today's dollars to the person who could first measure longitude accurately.

The contemporary cultural landscape approach to geography—

sometimes called the regional studies approach—was initiated

in France by Paul Vidal de la Blache (1845–1918) and Jean Brun-

hes (1869–1930). It was later adopted by several American geog-

raphers, including Carl Sauvage (1889–1973) and Robert Flan-

(1880–1950). Sauvage defined cultural landscape as an area fas-

hioned from nature by a cultural group. "Culture is the agent," he

said, "that in the real world, characteristics are integrated."

Cultural landscape geographers argue that each region has

its own distinctive landscape that results from a unique combi-

nation of social relationships and physical processes. People,

activities, and environments differ in some way from regularities

within a region and differ in some way from those of other

regions. A region's uniqueness from possessing not a single

human or environmental characteristic, but a combination of

humans. Not content to merely identify differences among

geographers seek relationships among them. Geographers rec-

ognize that in the real world, characteristics are integrated.

The fundamental principle underlying the cultural landscape

approach is that people are the most important agents of change

to Earth's surface. The distinctive character of a particular land-

scape may derive in part from natural features, such as vegeta-

tion and soil. However, the physical environment is not always

the most significant factor in human decisions. People can last-

longer in a landscape by superimposing new forms on the physical

environment. For example, the critical factor in selecting a site

for a cotton textile factory is not proximity to a place where col-

location is growing. A more important factor is selecting a suitable

location to access to a supply of low-cost labor. Economic sys-

tems, political structures, living arrangements, religious prac-

tices, and human activities can produce distinctive landscapes

that do not stem primarily from physical characteristics.

The geographer's job is to sort out the associations among

various social characteristics, each of which is uniquely distin-

guished across Earth's surface. For example, geographers conclude

that areas develop in sub-Saharan Africa, Southwest Asia, and

other parts of the continent despite the fact that the dis-

tantions of important features, such as climate and resources,

do not match the political boundaries of individual countries.

The designation of "region" can be applied to any area larger

than a point and smaller than the entire planet. Geographers

most often apply the concept at one of two scales:

- Several neighboring countries that share important fea-
- Many localities within a country, such as those in southern
- Areas, such as those in Latin America.

Types of Regions

A particular place can be included in more than one region

and eventually three types of regions—formal, func-

tional, and vernacular.

Geographers identify three types of regions—formal, func-

tional, and vernacular.

Regions in common one or more distinctive characteristics. The

region or a homogeneous region, is an area within which every-

thing has in common one or more distinctive characteristics. The

shared feature could be a cultural value such as a common

Cultural Landscape

A region derives its unified character through the cultural

landscape—a combination of cultural features such as lan-

guage and religion, economic features such as lan-

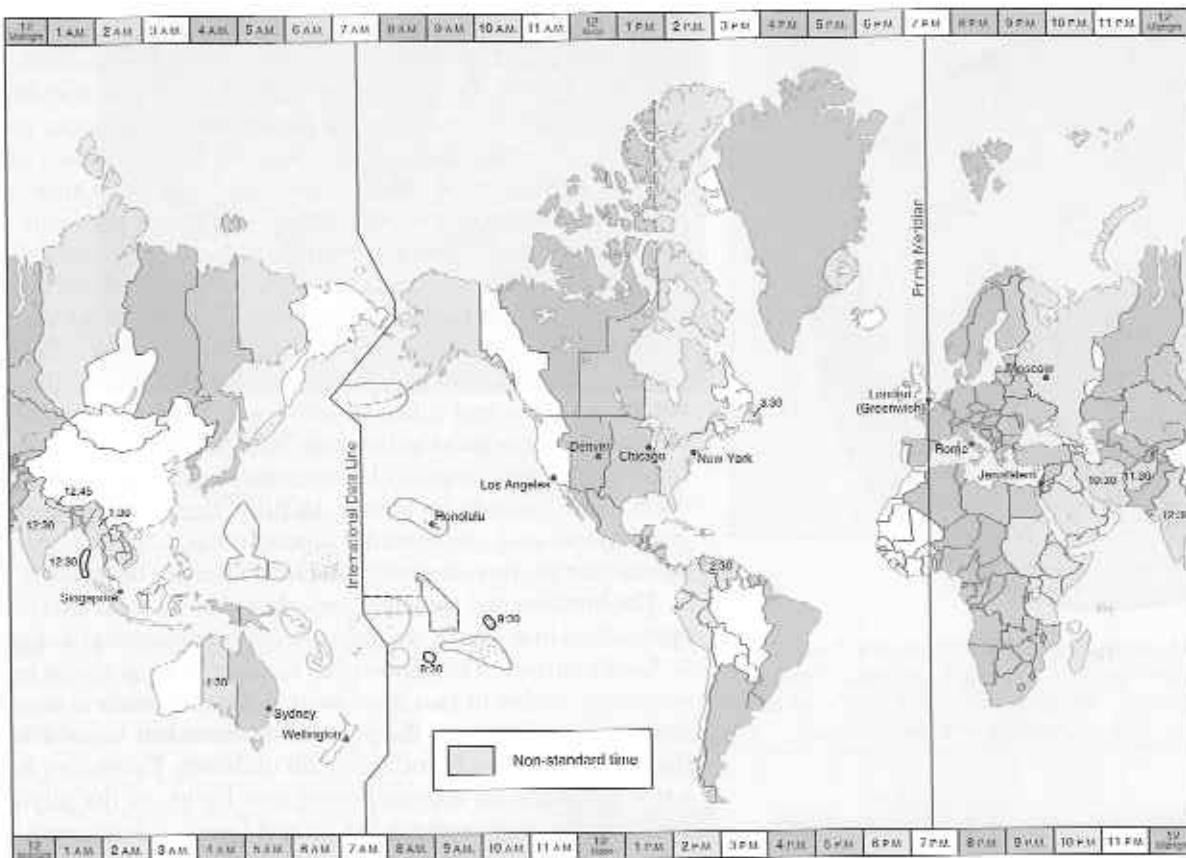

FIGURE 1-13 Time zones. Longitude plays an important role in calculating time. Earth as a sphere is divided into 360° of longitude (the degrees from 0° to 180° west longitude, plus the degrees from 0° to 180° east longitude).

As Earth rotates daily, these 360° imaginary lines of longitude pass beneath the cascading sunshine. If we let every fifteenth degree of longitude represent one time zone, and divide the 360° by 15° , we get 24 time zones, or one for each hour of the day. By international agreement, Greenwich Mean Time (GMT) or Universal Time (UT), which is the time at the prime meridian (0° longitude), is the master reference time for all points on Earth.

As Earth rotates eastward, any place to the east of you always passes "under" the Sun earlier. Thus as you travel eastward from the prime meridian, you are "catching up" with the Sun, so you must turn your clock ahead from GMT by 1 hour for each 15° . If you travel westward from the prime meridian, you are "falling behind" the Sun, so you turn your clock back from GMT by 1 hour for each 15° .

The eastern United States, which is near 75° west longitude, is therefore 5 hours earlier than GMT (the 75° difference between the prime meridian and 75° west longitude, divided by 15° per hour, equals 5 hours). Thus when the time is 11 AM GMT, the time in the eastern United States is 5 hours earlier, or 6 AM.

Each 15° band of longitude is assigned to a standard time zone. The 48 contiguous U.S. States and Canada share four standard time zones, known as Eastern, Central, Mountain, and Pacific:

- The Eastern Standard Time Zone is near 75° west longitude, which passes close to Philadelphia, and is 5 hours earlier than GMT.
- The Central Standard Time Zone is near 90° west longitude, which passes through Memphis, Tennessee, and is 6 hours earlier than GMT.
- The Mountain Standard Time Zone is near 105° west longitude, which passes through Denver, Colorado, and is 7 hours earlier than GMT.
- The Pacific Standard Time Zone is near 120° west longitude, which passes through Lake Tahoe in California, and is 8 hours earlier than GMT.

Most of Alaska is in the Alaska Time Zone, which is 9 hours earlier than GMT. Hawaii and some of the Aleutian Islands are in the Hawaii-Aleutian Time Zone, which is 10 hours earlier than GMT.

Eastern Canada is in the Atlantic Time Zone, which is 4 hours earlier than GMT. The residents of Newfoundland assert that their island, which lies between 53° and 59° west longitude, would face dark winter afternoons if it were 4 hours earlier than

GMT, like the rest of eastern Canada, and dark winter mornings if it were 3 hours earlier than GMT. Therefore, Newfoundland is $3\frac{1}{2}$ hours earlier than GMT.

Before standard time zones were created, each locality set its own time, usually that kept by a local jeweler. When railroads became the main cross-country transportation during the nineteenth century, each rail company kept its own time, normally that of the largest city it served. Train timetables listed two sets of arrival and departure times, one for local time and one for railroad company time. Railroad stations had one clock for local time and a separate clock for each of the railroad companies using the station.

To reduce the confusion from the multiplicity of local times, the railroads urged adoption of standard time zones. Standard time zones were established in the United States in 1883 and in the rest of the world following the international meridian conference in Washington, D.C., in 1884. At noon on November 18, 1883, time stood still in the United States so that each locality could adjust to the new standard time zones. In New York City, for example, time stopped for 3 minutes and 38 seconds to adjust to the new Eastern Standard Time.

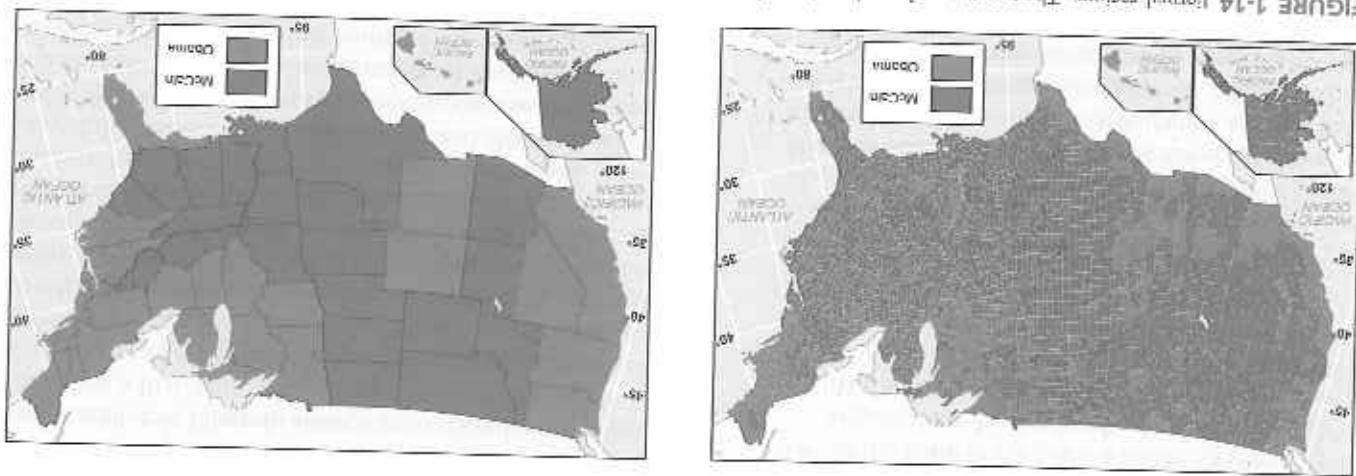

When you cross the International Date Line, which, for the most part, follows 180° longitude, you move the clock back 24 hours, or one entire day, if you are heading eastward toward America. You turn the clock ahead 24 hours if you are heading westward toward Asia.

To see the need for the International Date Line, try counting the hours around the world from the time zone in which you live. As you go from west to east, you add 1 hour for each time zone. When you return to your starting point, you will reach the absurd conclusion that it is 24 hours later in your locality than it really is.

Therefore, when the time in New York City is 2 PM, it is 7 PM Sunday in London, 8 PM Sunday in Rome, 9 PM Sunday in Jerusalem, 10 PM Sunday in Moscow, 3 AM Monday in Singapore, and 5 AM Monday in Sydney, Australia. Continuing farther east, it is 7 AM Monday in Wellington, New Zealand—but when you get to Honolulu, it is 9 AM Sunday, because the International Date Line lies between New Zealand and Hawaii.

The International Date Line for the most part follows 180° longitude. However, in 1997, Kiribati, a collection of small islands in the Pacific Ocean, moved the International Date Line 3,000 kilometers (2,000 miles) to its eastern border near 150° west longitude. As a result, Kiribati is the first country to see each day's sunrise. Kiribati hoped that this feature would attract tourists to celebrate the start of the new millennium on January 1, 2000 (or January 1, 2001, when sticklers pointed out the new millennium really began). But it did not.

FIGURE 1-14 *Inland regions.* The two maps show the winter by country (left) and state (right) in the 2000 presidential election. Counties and states are examples of formal regions. The extensive areas of support for George W. Bush (blue) and Michael Dukakis (red) are also examples of formal regions. While urban centers (left), built most of these were in rural areas, while population was lower than in the urban centers.

WENNERGAARD REGION. A vernacular region, or periphery cultural identity such regions emerge from people's empirical region, is a place that people believe exists as part of their cultural identity Such regions emerge from people's

VERNACULAR REGION

Customers can shop at distant stores by mail or the Internet.

Other examples of functional regions include the current union area of a newspaper and the reading area of a department store. A newspaper dominates circulation figures in the city in which it is published. Farther away from the city, fewer people read than newspaper, whereas more people read a newspaper published in a neighboring city. A department store attracts fewer customers from the edge of a trading area, and beyond that edge customers will most likely choose to shop elsewhere. New technology is breaking down traditional functional regions. Television stations are broadcast to distant places by satellite. Newspapers such as USA Today, The Wall Street Journal, and the New York Times are composed in one place, transmitted to yet other places by airplane, truck, or the Internet, and delivered to yet other places by satellite.

An example of a hemicentral region is the reception area of television station. A television station's signal is strongest at the center of its service area, becomes weaker at the edge, and finally can no longer be distinguished from snow (Figure 1-15). At some distance from the center, more people are walking between the nodal regions of the two markets.

to the surrounding area.

of service, and the boundaries of the region mark the limits of the trading area of the society. People and activities may be attracted to the node and扩散出去.

Geographers often use functional regions to display information about economic areas. The regions made may be a shape

The regional focus or mode and dimensions in importance outline the region is tied to the central point by transportation or communication systems as by economic or political

FUNCTONAL REGION. A functional region, also called nodal region, is an area organized around a node or focal point. The characteristics chosen to define a functional region dominate

A continental step in indefinitely formal regions is the need to recognize the diversity of cultural, economic, and environmental factors, even while making a generalization. Problems may arise because a majority of people in a region speak a language, practice a religion, or possess resources different from those in the majority. People in a region play distinctive roles in their economy and hold different positions in society based on their gender or ethnicity.

Similarly, we can distinguish formal regions within the region where corn is the most common crop. Limited states characterized by a predominantly voting for Republicans candidates, although Republicans do not get 100 percent of the votes in these regions—not in fact do they always win (Figure 1-14, left). However, in a presidential election, the candidate with the largest number of votes receives all of the electoral votes of a state, regardless of the margin of victory. Consequently, a state that usually has Democratic electors can be considered a Democratic state (Figure 1-14, right).

Some formal regions are easy to identify, such as countries or local governments units. Montana is an example of a formal region, characterized with equal intensity throughout the state by a government that passes laws, collects taxes, and issues license plates. The formal region of Montana has clearly drawn and legally recognized boundaries, and everyone living within them shares the status of being subject to a common set of laws. In other kinds of formal regions a characteristic may be pre-dominant rather than universal. For example, the North American wheat belt is a formal region in which wheat is the most commonly grown crop, but other crops are grown there as well. And the wheat belt can be distinguished from the corn belt—a

language, an economic activity such as production of a particular crop, or an environmental property such as climate. In a formal language, the intended interpretation of the present sentence

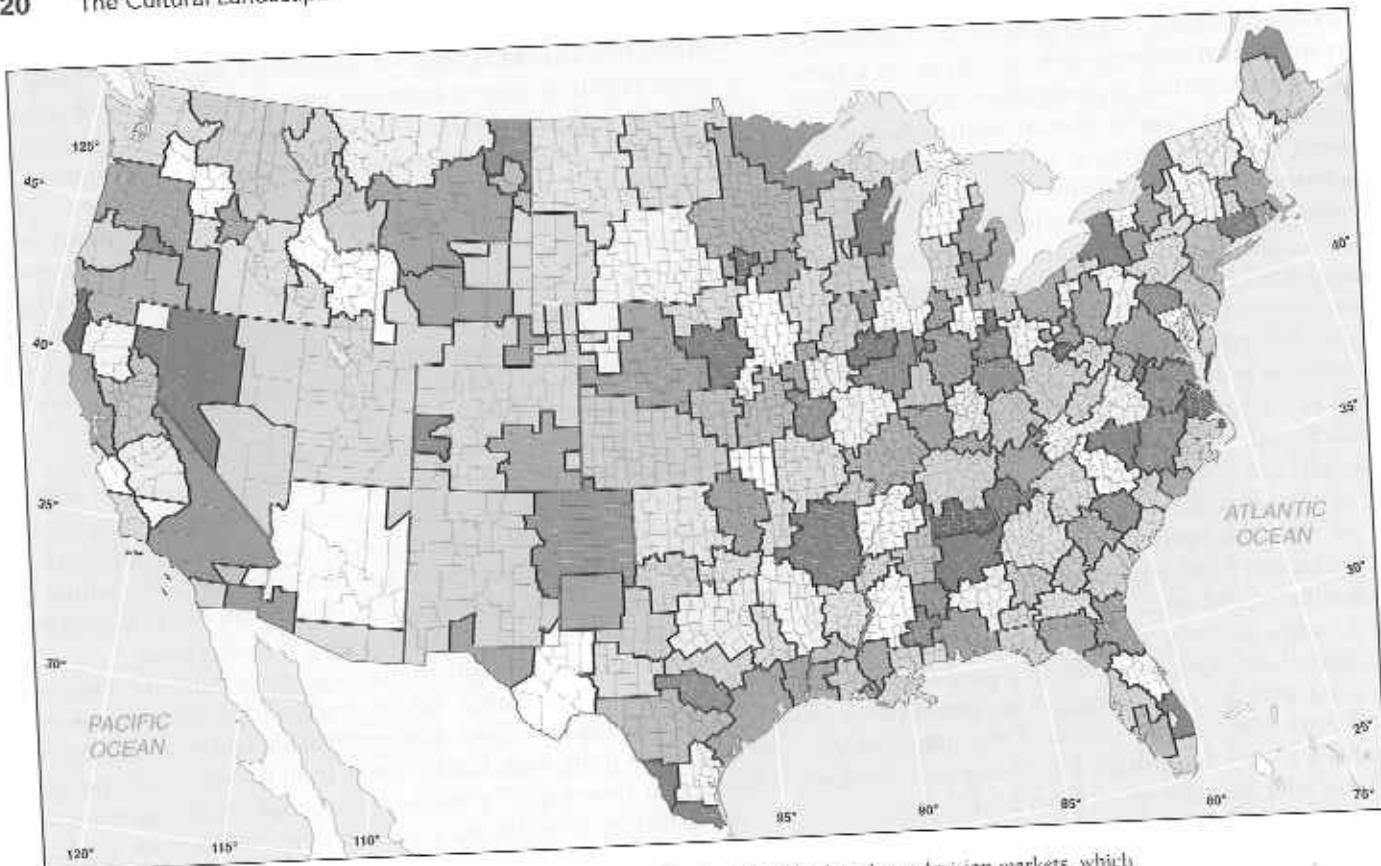

FIGURE 1-15 Functional regions. The United States is divided into functional regions based on television markets, which are groups of counties served by a collection of TV stations. Many of these TV market functional regions cross state lines.

informal sense of place rather than from scientific models developed through geographic thought.

A useful way to identify a perceptual region is to get someone to draw a **mental map**, which is an internal representation of a portion of Earth's surface. A mental map depicts what an individual knows about a place, containing personal impressions of what is in a place and where places are located. A student and a professor are likely to have different mental maps of a college campus, based on differences in where they work, live, and eat, and a senior is likely to have a more detailed and "accurate" map than a first-year student.

As an example of a vernacular region, Americans frequently refer to the South as a place with environmental, cultural, and economic features perceived to be quite distinct from the rest of the United States (Figure 1-16). Many of these features can be measured. Economically, the South is a region of high cotton production and low high school graduation rates. Culturally, the South includes the states that joined the Confederacy during the Civil War and where Baptist is the most prevalent religion. Environmentally, the South is a region where the last winter frost occurs in March, and rainfall is more plentiful in winter than in summer. Southerners and other Americans alike share a strong sense of the American South as a distinctive place that transcends geographic measurement. The perceptual region known as the South is a source of pride to many Americans—and for others it is a place to avoid.

Spatial Association

A region can be constructed to encompass an area of widely varying scale, from a very small portion of Earth to a very large portion. Different conclusions may be reached concerning a region's characteristics depending on its scale. Consider the percentage of Americans who die each year from cancer. Death rates vary widely among scales within the United States (Figure 1-17).

- At the scale of the United States, the Great Lakes and Southeastern regions have higher levels of cancer than the West.
- At the scale of the state of Maryland, the eastern region has a higher level of cancer than the western region.
- At the scale of the city of Baltimore, Maryland, lower levels of cancer are found in the northern region.

Maps showing regions of high and low cancer rates communicate useful information to someone who knows about the regions. To explain why regions possess distinct features, such as a high cancer rate, geographers try to identify cultural, economic, and environmental factors that display similar spatial distributions. Geographers conclude that factors with similar distributions have spatial association. By integrating other spatial information about people, activities, and environments, we can begin to see factors that may be associated with regional differences in cancer.

At the national scale, the Great Lakes region may have higher cancer rates in part because the distribution of ca-

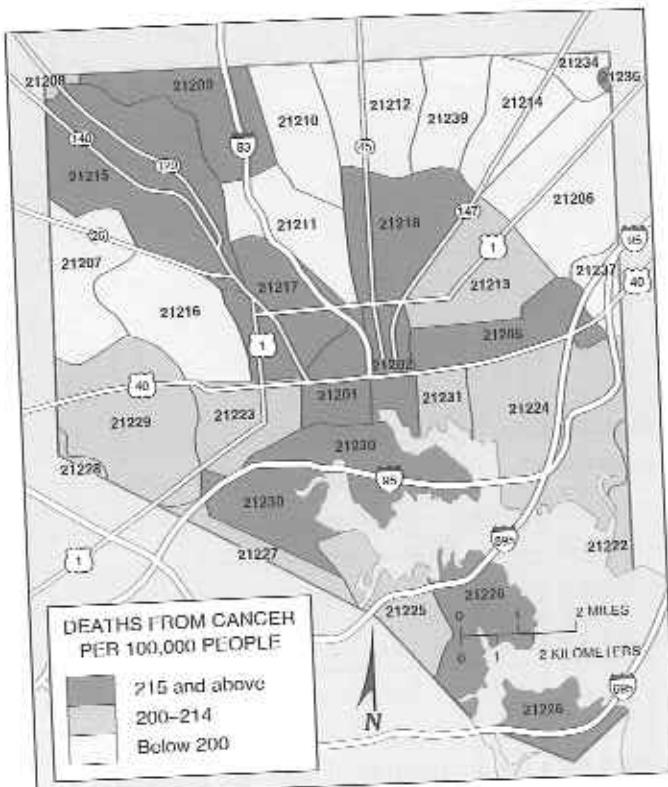

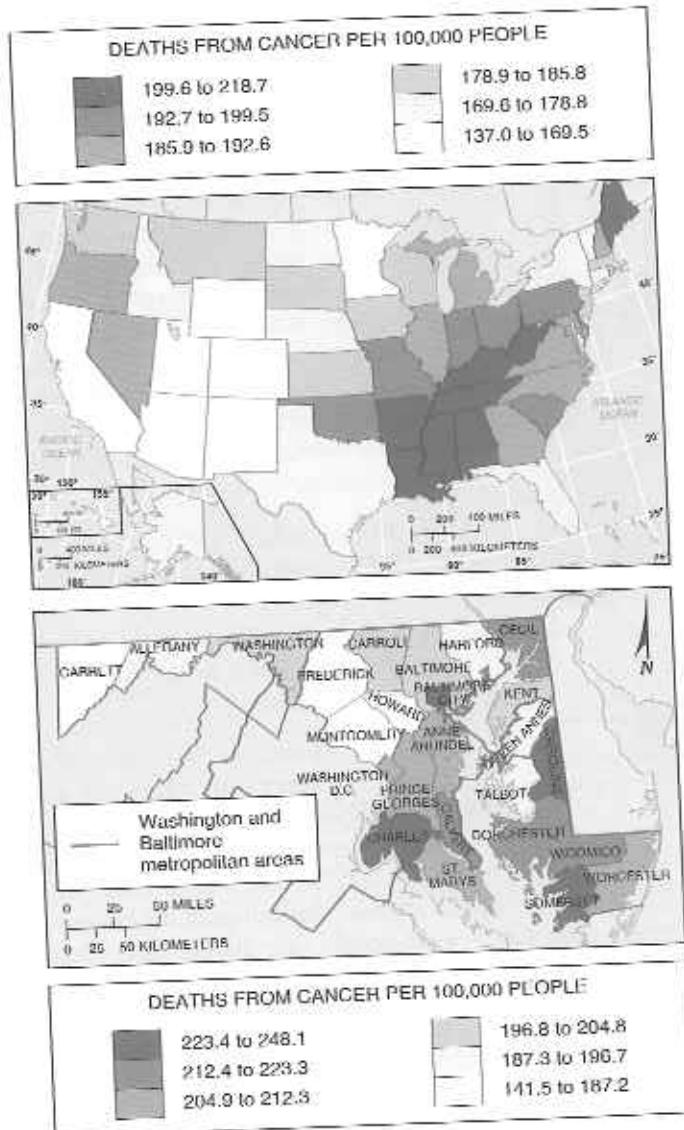

FIGURE 1-17 Spatial association. On the national scale, the Great Lakes and South regions have higher cancer rates than the Western region. On the scale of the state of Maryland, the eastern region has a higher cancer rate than the western region. On the urban scale, southern and northwestern neighborhoods of Baltimore City have higher cancer rates than northeastern ones. Geographers try to understand the reason for these variations.

its common traditions and heredity. As addressed in Chapter 7, geographers find that problems of conflict and inequality tend to occur in places where more than one ethnic group inhabits and seeks to organize the same territory.

WHAT PEOPLE TAKE CARE OF. The second element of culture of interest to geographers is production of material wealth—the food, clothing, and shelter that humans need in order to survive and thrive. All people consume food, wear clothing, build shelter, and create art, but different cultural groups obtain their wealth in different ways.

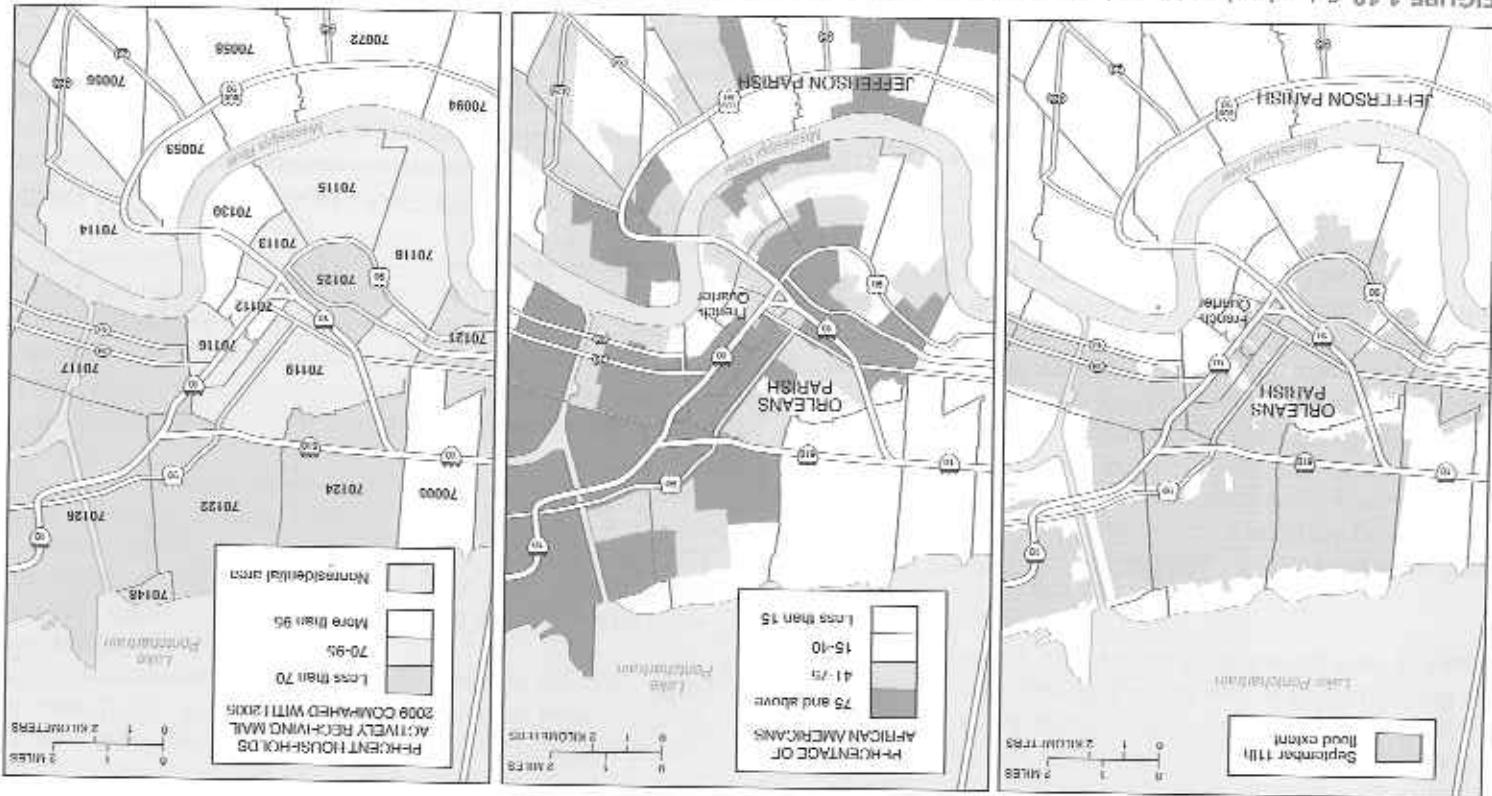

Geographers divide the world into regions of more (or relatively) developed countries (abbreviated MDCs), and regions of less developed (or developing) countries (abbreviated LDCs). Regions of MDCs include North America, Europe, and Japan, and regions of LDCs include sub-Saharan Africa, the Middle East, East Asia, South Asia, Southeast Asia, and Latin America. Various shared characteristics—such as per capita income, literacy rates, televisions per

capita, and hospital beds per capita—distinguish regions of MDCs and regions of LDCs. These differences are reviewed in Chapter 9.

Possession of wealth and material goods is higher in MDCs because of different types of economic activities than those in LDCs. Most people in LDCs are engaged in agriculture, whereas most people in MDCs earn their living through manufacturing products or performing services in exchange for wages. This fundamental economic difference between MDCs and LDCs is discussed in more detail in Chapters 10 through 13.

Geographers are also interested in the political institution that protect material artifacts, as well as cultural values. The world is organized into a collection of countries, or states, controlled by governments put in place through various representative and unrepresentative means. A major element of group's cultural identity is its citizenship, the country or countries that it inhabits and in which it pays taxes, votes, and otherwise participates in the administration of space.

FIGURE 1-18 Cultural ecology: New Orleans after Hurricane Katrina. From a physical perspective, the picture of New Orleans was underwater after the city's flood-prone levees broke (left). The 20 percent that was not flooded was land at slightly higher elevations, including the leading initial desimations in the Vieux Carré (French Quarter). From a social perspective, the population in the area that was not flooded was less than one-fourth African American. The percentage of homes that have been fixed up and reoccupied since the hurricane is lower in the areas that had relatively large African American populations (right).

GLOBAL FORCES, LOCAL IMPACTS

quarters, were spared the worst because they were located on slightly higher ground. The slow and incomplete response to the destruction by local, state, and federal emergency teams was attributed by many analysts to the victims' lack of a voice in the political, economic, and social life of New Orleans and other impacted communities.

After the hurricane (Figure 1-1B, right), more than 90 percent of households in the hurricane-prone areas were back in their homes, as measured by whether they were receiving mail. In contrast, less than two-thirds of the households in severely flood-prone areas were back in their homes, as measured by whether they were receiving mail. In the most severely affected areas, nearly half of the households in the hurricane-prone areas were still without power three weeks after the storm, while only one-quarter of the households in the less severely affected areas had no power.

The 2009, four years after the hurricane, survey found that nearly all of the households in the severely affected areas had been replaced by new ones. The replacement rate was highest in the most severely affected areas, where nearly all of the households had been replaced by new ones. The replacement rate was lowest in the least severely affected areas, where only about half of the households had been replaced by new ones.

These low-lying cities from flooding, government agencies constructed a complex system of levees, dikes, sea walls, canals, and pumps. The experience of Katrina proved that humans are not able to control and tame all of the forces of nature.

Human geographers are especially concerned with the uneven impact of desertification. Droughts, hurricanes, and new oil fields have caused many Americans, African Americans, and New Orleans, Louisiana. In an effort to protect these low-lying cities from flooding, government agencies constructed a complex system of levees, dikes, sea walls, canals, and pumps. The experience of Katrina proved that humans are not able to control and tame all of the forces of nature.

Human geographers are especially concerned with the uneven impact of desertification. In an effort to protect these low-lying cities from flooding, government agencies constructed a complex system of levees, dikes, sea walls, canals, and pumps. The experience of Katrina proved that humans are not able to control and tame all of the forces of nature.

Physical Geography concepts explain the process by which hurricanes, such as Katrina, form in the Atlantic Ocean during the late summer and autumn months. The warm waters of the Gulf of Mexico. When it passes over land, a hurricane can generate a powerful storm surge that floods low-lying areas including the cities of Biloxi and Gulfport, Mississippi. In part because it made massive damage, Katrina caused geographic injury. In addition, it is here that physical and human geography damage, in part because it made

As discussed in Chapter 8, cultural groups in the modern world are increasingly asserting their right to organize their own affairs at the local scale rather than submit to the control of other cultural groups. Political problems are found in places where the area occupied by a cultural group does not coincide with the boundaries of a country.

Cultural Ecology: Integrating Culture and Environment

In constructing regions, geographers consider environmental as well as cultural factors. Distinctive to geography is the importance given to relationships between culture and the natural environment. Different cultural groups modify the natural environment in distinctive ways to produce unique regions. The geographic study of human–environment relationships is known as **cultural ecology**.

Pioneering nineteenth-century German geographers Alexander von Humboldt (1769–1859) and Carl Ritter (1779–1859) urged human geographers to adopt the methods of scientific inquiry used by natural scientists. They argued that the scientific study of social and natural processes is fundamentally the same. Natural scientists have made more progress in formulating general laws than have social scientists, so an important goal of human geographers is to discover general laws.

According to Humboldt and Ritter, human geographers should apply laws from the natural sciences to understanding relationships between the physical environment and human actions. Humboldt and Ritter concentrated on how the physical environment caused social development, an approach called **environmental determinism**.

Other influential geographers adopted environmental determinism in the late nineteenth and early twentieth centuries. Friedrich Ratzel (1844–1904) and his American student, Ellen Churchill Semple (1863–1932), claimed that geography was the study of the influences of the natural environment on people.

Another early American geographer, Ellsworth Huntington (1876–1947), argued that climate was a major determinant of civilization. For instance, according to Huntington, the temperate climate of maritime northwestern Europe produced greater human efficiency as measured by better health conditions, lower death rates, and higher standards of living.

HUMAN AND PHYSICAL FACTORS. To explain relationships between human activities and the physical environment in a region, modern geographers reject environmental determinism in favor of possibilism. According to **possibilism**, the physical environment may limit some human actions, but people have the ability to adjust to their environment. People can choose a course of action from many alternatives in the physical environment. Humans endow the physical environment with cultural values by regarding it as a collection of **resources**, which are substances that are useful to people, economically and technologically feasible to access, and socially acceptable to use.

For example, the climate of any location influences human activities, especially food production. From one generation to the next, people learn that different crops thrive in different climates—rice requires plentiful water, whereas wheat survives on limited moisture and actually grows poorly in very wet environments. On the other hand, wheat is more likely than rice to be grown successfully in colder climates. Thus, under possibilism, it is possible for people to choose the crops they grow and to be compatible with their environment.

Human geographers use this cultural ecology, or human–environment, approach to explain many global issues. For example, world population growth is a problem if the number of people exceeds the capacity of the physical environment to produce food. However, people can adjust to the capacity of the physical environment by controlling their numbers, adopting new technology, consuming different foods, migrating to new locations, and taking other actions.

Some human impacts on the environment are casual, and some are based on deep-seated cultural values. Why do we plant our front yard with grass, water it to make it grow, mow it to keep it from growing tall, and impose fines on those who fail to mow often enough? Why not let dandelions grow or pour concrete instead? Why does one group of people consume the fruit from deciduous trees and chop down the conifers for building materials, whereas another group chops down the deciduous trees for furniture while preserving the conifers as religious symbols?

A people's level of wealth can also influence its attitude toward modifying the environment. A farmer who possesses a tractor may regard a hilly piece of land as an obstacle to avoid, but a poor farmer with a hoe may regard hilly land as the only opportunity to produce food for survival through hand cultivation.

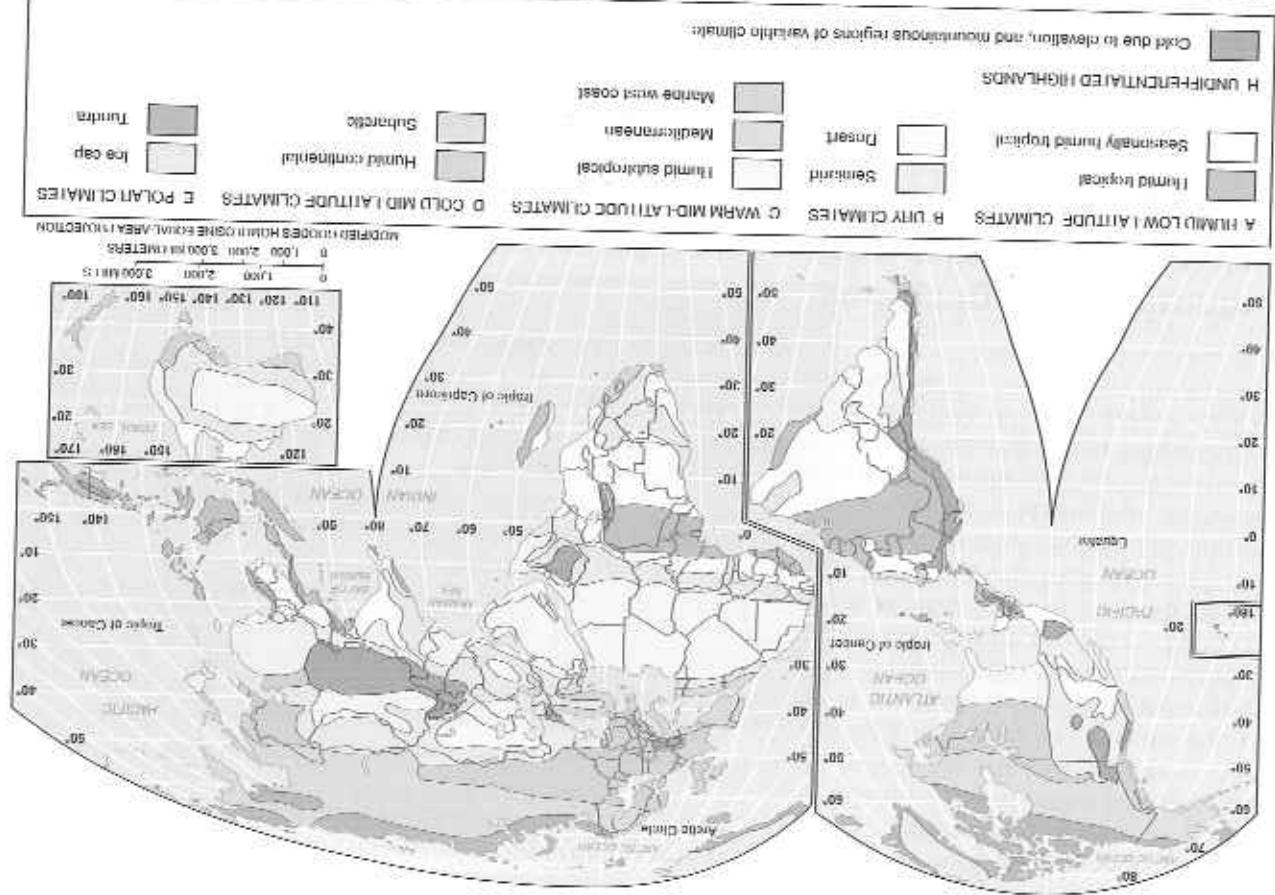

PHYSICAL PROCESSES: CLIMATE. Human geographers need some familiarity with global environmental processes to understand the distribution of human activities, such as where people live and how they earn a living. Important physical processes include climate, vegetation, soil, and landforms.

Climate is the long-term average weather condition at a particular location. Geographers frequently classify climates according to a system developed by German climatologist Vladimir Köppen. The modified Köppen system divides the world into five main climate regions that are identified by the letters A through E as well as by names:

- A Tropical Climates
- B Dry Climates
- C Warm Mid-Latitude Climates
- D Cold Mid-Latitude Climates
- E Polar Climates

The modified Köppen system divides the five main climate regions into several subtypes (Figure 1-19). For all but the B climate, the basis for the subdivision is the amount of precipitation and the season in which it falls. For the B climate, subdivision is made on the basis of temperature and precipitation.

developed by Valdimir Koppert. The modelled koppert system divides the world into five main climate regions, represented by the letters A, B, C, D, and E.

Forest biome. Trees form a continuous canopy over the ground; grasses and shrubs may grow beneath the cover. The forest biome covers a large percentage of Earth's surface, including much of North America, Europe, and Asia, as well as tropical areas of South America, Africa, and Southeast Asia.

Savanna biome. The trees do not form a continuous canopy and the resultant lack of shade allows grass to grow savanna covers large areas of Africa, South Asia, South America, and Australia.

Grazland biome. Land is covered by grass rather than trees; few trees grow in the region because of low precipitation. Early explorers from northern Europe and eastern North America regarded the American prairies—the

The climate of a particular location influences human activities, especially production of the food needed to survive. People in parts of the A climate region, especially southern India, Bangladesh, and the Myanmar (Burma) coast, annually await the annual monsoon rains, which is essential for success in agriculture and provides nearly 90 percent of India's water supply (Figure 1-20). For most of the year, the region receives dry, somewhat cool air from the northeast. In June, the wind direction suddenly shifts, bringing moist, warm, southerly air, known as the monsoon, from the Indian Ocean. The monsoon rain lasts until September. By years when the monsoon fails, there is a shortage of water in the region, the economy suffers, and people live in poverty.

PHYSICAL PROCESSES: VEGETATION. Plant life covers nearly the entire land surface of Earth. Land vegetation includes four major forms of plant communities: *deserts*, *forests*, *savanna*, and *tundra*.

FIGURE 1-20 Monsoon in India. Camels graze on a sand dune turned green by summer monsoon rains in Mathania, Rajasthan state, India.

world's most extensive grassland area—to be uninhabitable because of the lack of trees with which to build houses, barns, and fences. However, modern cultivation of wheat and other crops has turned the grasslands into a very productive region.

- **Desert biome.** Although many desert areas have essentially no vegetation, the region contains dispersed patches of plants adapted to dry conditions. Vegetation is often sufficient for the survival of small numbers of animals.

PHYSICAL PROCESSES: SOIL. Soil, the material that forms on Earth's surface, is the thin interface between the air and the rocks. Not merely dirt, soil contains the nutrients necessary for successful growth of plants, including those useful to humans. The U.S. Comprehensive Soil Classification System divides global soil types into twelve orders, according to the characteristics of the immediate surface soil layers and the subsoil. The orders are subdivided into suborders, great groups, subgroups, families, and series. More than 12,000 soil types have been identified in the United States alone. Human geographers are concerned with the destruction of the soil that results from a combination of natural processes and human actions. Two basic problems contribute to the destruction of soil—erosion and depletion of nutrients.

Erosion occurs when the soil washes away in the rain or blows away in the wind. To reduce the erosion problem, farmers reduce the amount of plowing, plant crops whose roots help bind the soil, and avoid planting on steep slopes.

Nutrients are depleted when plants withdraw more nutrients than natural processes can replace. Each type of plant withdraws certain nutrients from the soil and restores others. Repeated harvesting of the same type of crop year after year can remove certain nutrients and reduce the soil's productivity. To minimize depletion, farmers in MDCs sometimes plant crops

that offer no economic return but restore nutrients to the soil and keep the land productive over a longer term. Farmers also restore nutrients to the soil by adding fertilizers, either natural or synthetic. Farmers in LDCs may face greater problems with depletion of nutrients because they lack knowledge of proper soil management practices and funds to buy fertilizer.

PHYSICAL PROCESSES: LAND-FORMS.

Earth's surface features, or landforms, vary from relatively flat to mountainous. Geographers find that the study of Earth's landforms—a science known as geomorphology—helps to explain the distribution of people and the choice of economic activities at different locations. People prefer living on flatter land, which generally is better suited for agriculture. Great concentrations of people and activities in hilly areas may require extensive effort to modify the landscape.

Topographic maps, published (for the United States) by the U.S. Geological Survey (USGS), show a remarkable detail of physical features, such as bodies of water, forests, mountains, valleys, and wetlands. They also show cultural features, such as buildings, roads, parks, farms, and dams. "Topos," as they are called, are used by engineers, hikers, hunters, people seeking a homesite, and anyone who really needs to see the lay of the land. Geographers use topographic maps to study the relief and slope of localities. Relief is the difference in elevation between any two points, and it measures the extent to which an area is flat or hilly. The steepness of hills is measured by slope, which is the relief divided by the distance between two points. Figure 1-5 shows a portion of a USGS map for northern Mississippi, at the scale of 1:24,000. The brown lines on the map are contour lines that connect points of equal elevation above or below sea level. Contour lines are closer together to show steeper slopes and farther apart in flatter areas.

Modifying the Environment

Modern technology has altered the historic relationships between people and the environment. Humans now can modify a region's physical environment to a greater extent than in the past. Geographers are concerned that people sometimes use modern technology to modify the environment inefficiently. Human actions can deplete scarce environmental resources, destroy irreplaceable resources, and use resources inefficiently.

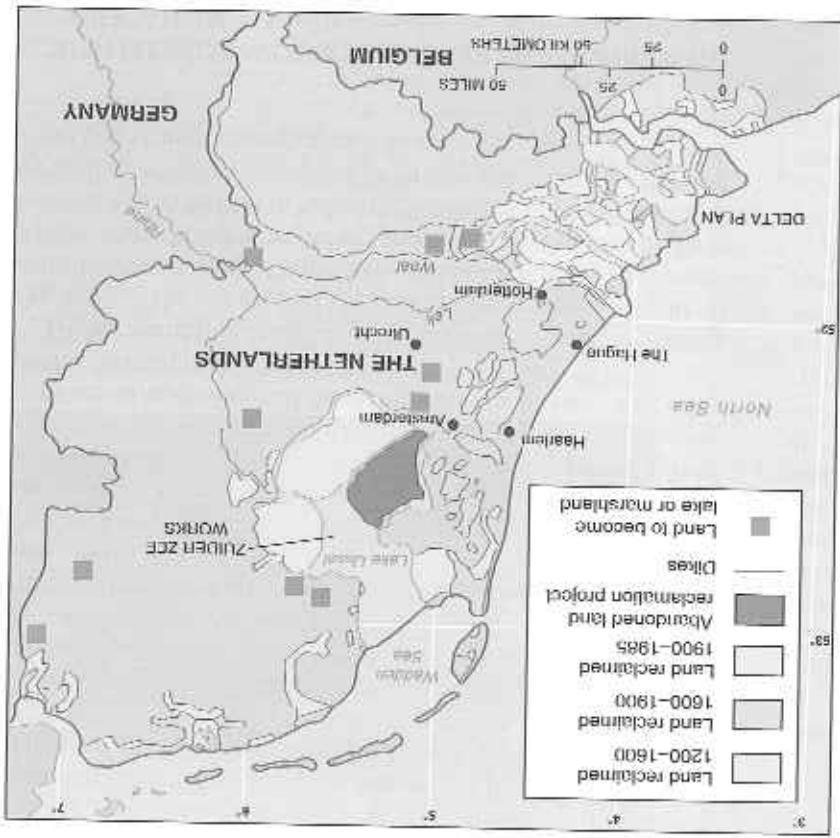

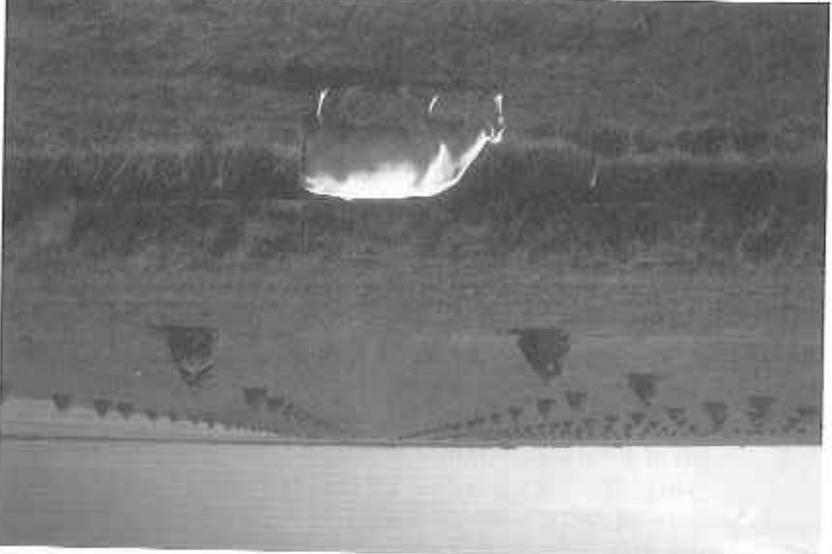

For example, air-conditioning has increased the attractiveness of living in regions with warmer climates. But the refrigerants used in air conditioners have also increased the amount of chlorofluorocarbons in the atmosphere, damaging the ozone layer that protects living things from UV rays and contributing to global warming.

After a devastating flood in 1933, the Delta Plan built dikes to close off most of the waterways in the southwestern part of the County because Rotterdam, Fritsop's largest port, is located nearby, some of the waterways were kept open. The Delta Works are barely visible in the background of the photograph of a polder.

In the late Paleozoic environment, which marginally contains large trilobites, sandy sediments were deposited in embayments along the margin of the Zuidster Zee. The bedrock of the North Sea is composed of the bedrock of the Zuidster Zee, which is a thick, light-colored limestone. This limestone is composed of dolomite, which is a mineral that is formed by the dissolution of calcium carbonate. The dolomite is composed of dolomite, which is a mineral that is formed by the dissolution of calcium carbonate. The dolomite is composed of dolomite, which is a mineral that is formed by the dissolution of calcium carbonate.

HIGHLIGHT 1-21 Dutchmen's ability to estimate cultural needs in the Netherlands. The Dutch people have consistently altered the site of the Netherlands' creation of policies and dilemmas. In the first step in making a policy is to build a wall separating the site from the water. Then the water inside the wall is pumped from the site to either nearby canals or the remaining portion of the original body of water. Once dry, the site is prepared for the remaining portion of the original body of water.

[View Details](#)

The second ambitious project in the Netherlands is the Delta Plan in the southwestern part of the country. Flowing through the Netherlands are several important rivers, including the Rhine (Europe's busiest river), the Maas (known as the Meuse in France), and the Scheldt (known as the Schelde in Belgium). As these rivers flow into the North Sea, they split into many branches and form a low-lying delta that is vulnerable to flooding. After a devastating flood in January 1953 killed nearly 2,000 people, a plan was developed to protect the land from future floods.

The second distinctive modification of the land-scape in the Netherlands is the construction of massive dikes to prevent the North Sea, an arm of the Atlantic Ocean, from flooding much of the country. The Dutch have built dikes in two major locations—the Zuider Zee project in the north and the Delta Plan project in the southwest.

The Zuider Zee, an arm of the North Sea, once threatened the heart of the Netherlands with floods. A dike completed in 1932 caused the Zuider Zee to be converted from a saltwater sea to a freshwater lake. The newly created body of water was named Lake IJsselmeer, or Lake IJssel, because the IJssel River now flows into it. Some of the lake has been drained to create several polders, enclosures

lying an area of 1,600 square kilometres (620 square miles) that now flows into it. Some of the lake has been drained to create several polders, enclosures

A polder is a piece of land that is created by draining water from an area. Polders, first created in the thirteenth century, were constructed primarily by private developers in the Netherlands and seventeenth century. All together, the Netherlands has 6,500 square kilometers (2,600 square miles) of polders, comprising 16 percent of the country's land area (Figure 1-21). The Dutch government has reserved most of the polders for agriculture to reduce the country's dependence on imported food. Some of the polders are used for housing, and one community, Schiphol, one of Europe's busiest airports.

construction projects—polders and dikes.

THE NETHERLANDS: SENSITIVE ENVIRONMENTAL MODIFICATION. The Dutch have a saying that "God made Earth, but the Dutch made the Netherlands." The Dutch have modified their environment with two distinctive types of

New regions have been as thoroughly modified by humans as the Netherlands and Florida's Everglades.

warming. We explore the consequences of such use, abuse, and misuse of the environment in more detail.

people, the Delta Plan called for the construction of several dams to close off most of the waterways from the North Sea. The project took 30 years to build and was completed in the mid-1980s.

Once these two massive projects were finished, attitudes toward modifying the environment changed in the Netherlands. The Dutch scrapped plans to build additional polders in the IJsselmeer in order to preserve the lake's value for recreation.

The Dutch are deliberately breaking some of the dikes to flood fields. A plan adopted in 1990 called for returning 263,000 hectares (650,000 acres) of farms to wetlands or forests. Widespread use of insecticides and fertilizers on Dutch farms has contributed to contaminated drinking water, acid rain, and other environmental problems.

Global warming could threaten the Netherlands by raising the level of the sea around the country by between 20 and 58 centimeters (8 and 23 inches) within the next 100 years. Rather than build new dikes and polders, the Dutch have become world leaders in reducing the causes of global warming by acting to reduce industrial pollution and increase solar and wind power use, among other actions.

SOUTH FLORIDA: NOT-SO-SENSITIVE ENVIRONMENTAL MODIFICATION. Sensitive environmental areas in South Florida include barrier islands along the Atlantic and Gulf coasts, the wetlands between Lake Okeechobee and the Everglades National Park, and the Kissimmee River between Lake Kissimmee and Lake Okeechobee (Figure 1-22). These lowlands have been modified less sensitively than those in the Netherlands.

The Everglades was once a very wide and shallow freshwater river 80 kilometers (50 miles) wide and 15 centimeters (6 inches) deep, slowly flowing south from Lake Okeechobee to the Gulf of Mexico. A sensitive ecosystem of plants and animals once thrived in this distinctive landscape, but much of it has been destroyed by human actions.

The U.S. Army Corps of Engineers built a levee around Lake Okeechobee during the 1930s, drained the northern one-third of the Everglades during the 1940s, diverted the Kissimmee River into canals during the 1950s, and constructed dikes and levees near Miami and Fort Lauderdale during the 1960s. The southern portion of the Everglades became a National Park. These modifications opened up hundreds of thousands of hectares of land for growing sugarcane and protected farmland as well as the land occupied by the growing South Florida population from flooding. But they had unintended consequences for South Florida's environment.

Polluted water mainly from cattle grazing along the banks of the canals flowed into Lake Okeechobee, which is the source of fresh water for half of Florida's population. Fish in the lake began to die from the high levels of mercury, phosphorous, and other contaminants. The polluted water then continued to flow south into the National Park, threatening native vegetation such as sawgrass and endangering rare birds and other animals.

Meanwhile, Florida's barrier islands are home to several hundred thousand people. These barrier islands, as well as those elsewhere along the Atlantic and Gulf coasts between Maine and Texas, are essentially large sandbars that shield the mainland from flooding and storm damage. They are constantly being eroded and shifted from the force of storms and pounding surf, and after a major storm, large sections are sometimes washed away. Despite their fragile condition, the barrier islands are attractive locations for constructing homes and recreational facilities to take advantage of proximity to the seashore. Most of the barrier islands are linked with the mainland by bridge, causeway, or ferry service. To fight erosion along the barrier islands, people build seawalls and jetties, which are structures extending into the sea, but these projects result in more damage than protection. A seawall or jetty can prevent sand from drifting away, but by trapping sand along the up-current side, it causes erosion on the barrier islands on the down-current side.

A 2000 plan called for restoring the historic flow of water through South Florida while improving flood control and water quality. A 2008 plan called for the state to acquire hundreds of thousands of acres of land from sugarcane growers. But to date, few elements of the plans to restore the Everglades have been implemented. One-half of the Everglades has been lost to development. In an ironic reminder of the Dutch saying quoted earlier, Floridians say, "God made the world in six days, and the Army Corps of Engineers has been tinkering with it ever since."

KEY ISSUE 3

Why Are Different Places Similar?

- Scale: From Local to Global
- Space: Distribution of Features
- Connections Between Places

Although accepting that each place or region on Earth is unique, geographers recognize that human activities are rarely confined to one location. Discussed in this section are three basic concepts—scale, space, and connection—that help geographers understand why two places in different regions can display similar features. ■

Scale: From Local to Global

Geographers think about scale at many levels, from local to global. At a local scale, such as an urban neighborhood, geographers tend to see unique features. At the global scale, encompassing the entire world, geographers tend to see broad patterns.

Scale is an increasingly important concept in geography because of globalisation, which is a form of process that involves the entire world and results in making something worldwide in scope. Globalisation means that the scale of the world is shrinking—not literally in size, of course, but in the ability of a person, object, or idea to interact with a person, object, or idea in another place.

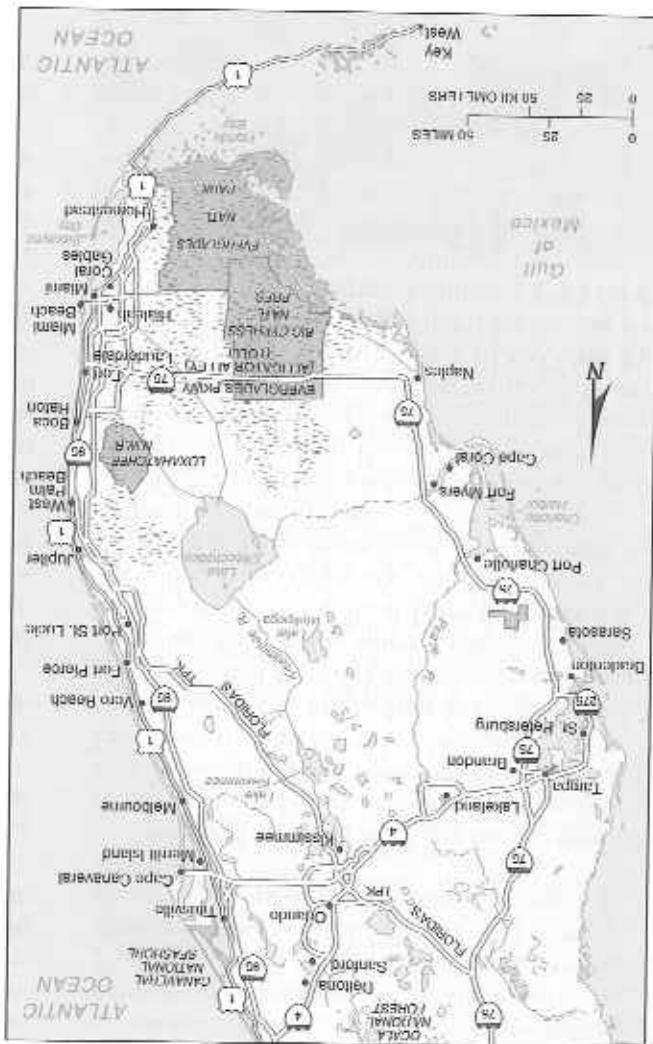

Globalization of Economy

A generation ago, people connected with environment quidly proclaimed, "Think global, act local." The phrase meant that the environment was being harmed by processes such as global warming that were global in scale, but it could be improved by actions, such as conserving less gasoline, that were local in scale. Contemporay geographers offer a different version of the phrase: "Think and act both global and local." All scales from local to global are important in geography—the appropriate scale depends on the specific subject.

Geography matters in the contemporary world because it can explain human actions at all scales, from local to global. At the national and international scales, geography is concerned with such questions as where the population is growing rapidly while corporations place factories. Geography also studies why these settlements can cause problems. Why can rapid population growth exceed available land supply? Why are different religious groups unable to live in peace with each other? Why are some places unable to attract or retain immigrants?

To control flooding in central Florida, the U.S. Army Corps of Engineers straightened the course of the Kissimmee River, which had meandered for 160 kilometers (96 miles) down near Orlando to Lake Okeechobee. The river's water was redirected into a canal 90 meters wide (300 feet) and 9 meters deep (30 feet), running in a straight line for 81 kilometers (52 miles). After the canal, known as C-38, opened in 1971, millions of gallons of polluted water—mainly runoff from cattle grazing—began gushing into Lake Okeechobee, which is the major source of freshwater about half of Florida's population. The U.S. Army Corps of Engineers has remedied the river's course to its original course (on the left side).

A black and white photograph showing a close-up view of a textured surface, possibly a wall or a piece of fabric, with a prominent diagonal crease or fold running from the bottom left towards the top right.

But most economic activities undertaken in one region are influenced by interaction with decision makers located elsewhere. The choice of crop is influenced by demand and prices set in markets elsewhere. The factory is located to facilitate bringing in raw materials and shipping out products to the markets.

Globalization of the economy has been led primarily by transnational corporations, sometimes called multinational corporations (Figure 1-23). A **transnational corporation** conducts research, operates factories, and sells products in many countries, not just where its headquarters and principal shareholders are located.

Historically, people and companies had difficulty moving even small sums of money from one country to another. International transfer of money involved a cumbersome set of procedures, and funds could be frozen for several weeks until all of the paperwork cleared. Most governments prohibited the removal of large sums of money, and in the case of Communist countries, no money could be removed without government approval. Modern technology provides the means to easily move money—as well as materials, products, technology, and other economic assets—around the world. Thanks to the electronic superhighway, companies can now organize economic activities at a global scale.

Every place in the world is part of the global economy, but globalization has led to more specialization at the local level. Each place plays a distinctive role, based on its local assets. A place may be near valuable minerals, or it may be inhabited by especially well-educated workers. Transnational corporations assess the particular economic assets of each place. A locality may be especially suitable for a transnational corporation

to conduct research, to develop new engineering systems, to extract raw materials, to produce parts, to store finished products, to sell them, or to manage operations. In a global economy, transnational corporations remain competitive by correctly identifying the optimal location for each of these activities.

Globalization of the economy has heightened economic differences among places. Factories are closed in some locations and opened in others. Some places become centers for technical research, whereas others become centers for low-skilled tasks. Changes in production have led to a spatial division of labor, in which a region's workers specialize in particular tasks. Transnationals decide where to produce things in response to characteristics of the local labor force, such as level of skills, prevailing wage rates, and attitudes toward unions. Transnationals may close factories in locations with high wage rates and strong labor unions.

The deep recession that began in 2008 has been called the first global recession. Past recessions were typically confined to one country or region. For example, financial policies in Thailand triggered a severe recession there and in neighboring countries of Southeast Asia in 1997 but had little impact on the economies of the United States and Europe. In contrast, the global economy declined in 2009 for the first time in more than a half-century. Although every region suffered economic decline, the effects of the global recession varied. The fate of a home buyer in the United States was tied to the fate of a banker in United Kingdom, a sales clerk in Japan, a clothing maker in China, and a construction worker in Nigeria. All were caught in a global-scale web of falling demand and lack of credit.

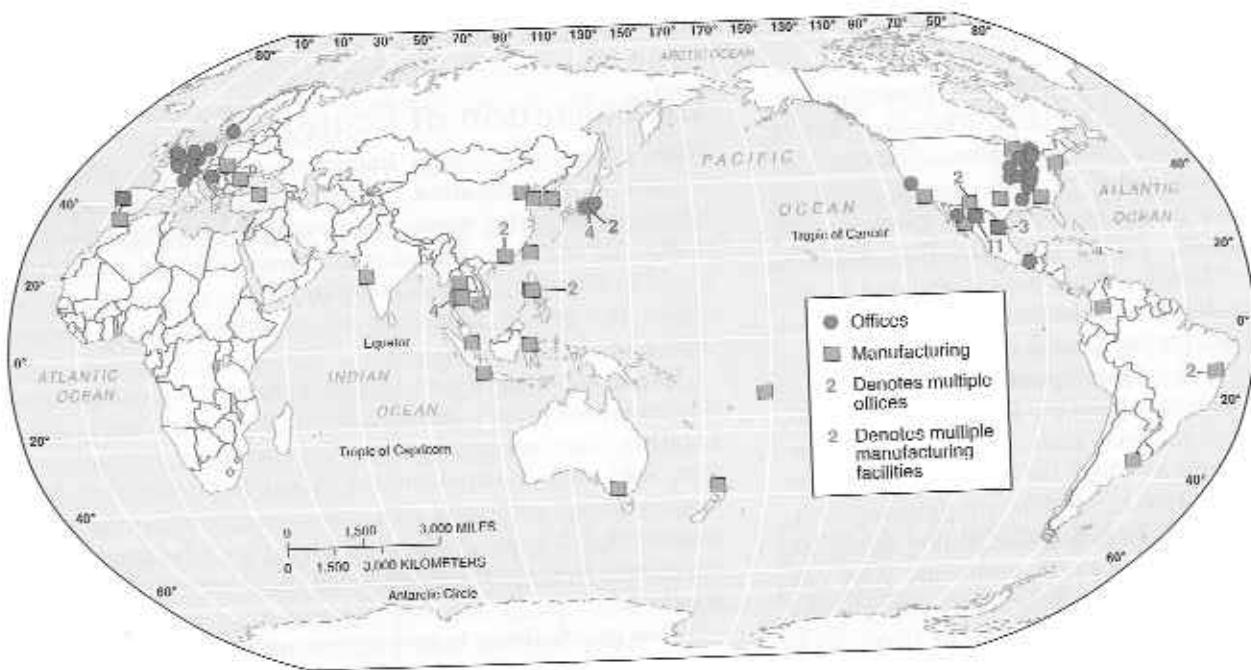

FIGURE 1-23 Globalization of economy Yazaki, a transnational corporation that makes parts for cars has factories primarily in Asia and Latin America, where labor costs are relatively low, and offices primarily in Europe, North America, and Japan, where most of the customers (carmakers) are located.

As more people become aware of elements of global culture and aspire to possess them, local cultural beliefs, forms, and artifacts are threatened with extinction. Yet despite globalization, cultural differences among places not only persist but actually flourish in many places. Global standardization of products does not mean that everyone wants the same cultural products.

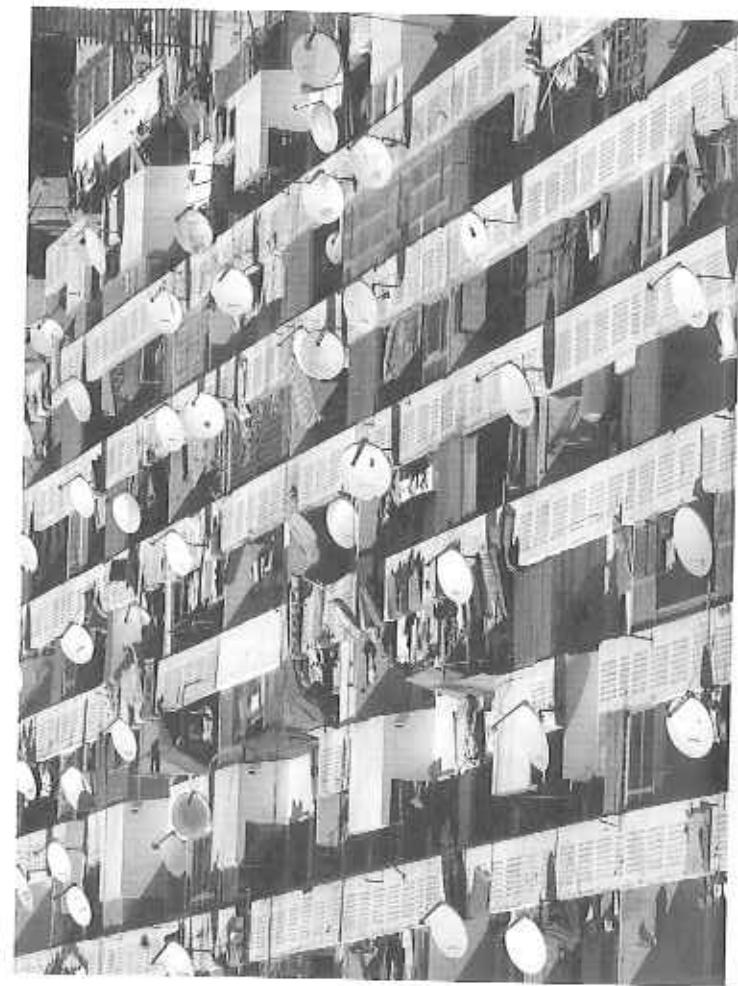

The communication revolution that promotes globalization is also limited to a handful of channels TV, for example, was once limited to a handful of channels that promote a narrow range of programming. Now people from around the world can choose from hundreds of programs in more than one language.

With the globalization of communications, people in two distant places can watch the same television program. At the same time, with the fragmentation of the broad casting market, local cultural traditions in the face of globalization led to a group to retain its strong determination on the part of a group to retain its control of Afghanistan (Chapter 8). Al-Qaeda supporters of September 11, 2001, with support from the Taliban, then in control of Afghanistan (Chapter 8), where different cultural trends in culture, politics, and the economy. Al-Qaeda's leaders justified such actions as banning television and restrictions on women's activities as being consistent with local traditions, and such punishments as public floggings and severe beatings as being necessary to share the same space peacefully (see Chapter 7).

A much more extreme opposition to globalization led to the attack by Al-Qaeda terrorists against the United States on September 11, 2001, with support from the Taliban, then in control of Afghanistan (Chapter 8). Al-Qaeda supporters have been unable to share the same space peacefully (see Chapter 7).

Similar tastes in different parts of the world, similar customs as wearing jeans and Nike shoes, consuming Coca-Cola and McDonald's hamburgers, and communicating through mobile phones and computers have moved Christianity away from traditional religions and have adopted Christianity or Islam, religions shared with hundreds of millions of people throughout the world. Globalization requires a form of common

of the world's highest per capita ownership of satellite dishes.

Globalization of Culture

Geographers observe that increasingly uniform cultural preferences produce uniform "global" landscapes of material artifacts and of cultural values (Figure 1-24). Houses built on the edge of one urban area will look very much like houses built on the edge of other regions. Fast-food restaurants, service stations, and retail chains deliberately create a visual appearance that varies among locations as little as possible. That way, customers know what to expect regardless of where they happen to be.

Regardless of local cultural traditions, people around the world aspire to drive an automobile, watch television, and own a house. The survival of a local cultural distinctive beliefs, forms, and rituals may be threatened by interaction with such social customs as wearing jeans and Nike shoes, consumption of Coca-Cola and McDonald's hamburgers, and communication by cell phone and computer. And communities hampered by religion and language. Africans, in particular, beliefs especially scarce is globalization of cultural beliefs and forms, especially those that are shared with billions of people from around the world. Globalization requires a form of common

As more people become aware of elements of global culture and the role of English language is increasingly played in the community, and the English language is increasing play-

Space: Distribution of Features

Chess and computer games, where pieces are placed on a grid-shaped playing surface, require thinking about space. Pieces are arranged on the game board or screen in order to outmaneuver an opponent or form a geometric pattern. To excel at these games, a player needs spatial skills, the ability to perceive the future arrangement of pieces. Similarly, spatial thinking is the most fundamental skill that geographers possess to understand the arrangement of objects across surfaces considerably larger than a game board. Geographers think about the arrangement of people and activities found in space and try to understand why those people and activities are distributed across space as they are.

In his framework of all scientific knowledge, the German philosopher Immanuel Kant (1724–1804) compared geography's concern for space to history's concern for time. Historians identify the dates of important events and explain why human activities follow one another chronologically. Geographers identify the location of important places and explain why human activities are located beside one another in space. Historians ask when and why. Geographers ask where and why. Historians organize material chronologically because they understand that an action at one point in time can result from past actions that can in turn affect future ones. Geographers organize material spatially because they understand that an action at one point in space can result from something happening at another point, which can consequently affect conditions elsewhere.

History and geography differ in one especially important manner: A historian cannot enter a time machine to study other eras firsthand; however, a geographer can enter an automobile or airplane to study other spaces. This ability to reach other spaces lends excitement to the discipline of geography—and geographic training raises the understanding of other spaces to a level above that of casual sightseeing.

Distribution

Look around the space you currently occupy—perhaps a classroom, residence hall, or room in a house. Tables, chairs, and other large objects are arranged regularly, such as in a row in a classroom or against a wall at home (though books and papers may be strewn about the space randomly). The room is located in a building that occupies an organized space—along a street, a side of a quadrangle, or next to a park. Similarly, the community containing the campus or house is part of a system of communities arranged across the country and around the world.

Each building and community, as well as every other human or natural object, occupies a unique space on Earth, and geographers explain how these features are arranged across Earth. On Earth as a whole, or within an area of Earth, features may be numerous or scarce, close together or far apart. The arrangement of a feature in space is known as its **distribution**. Geographers identify three main properties of distribution across Earth—density, concentration, and pattern (Figure 1-25).

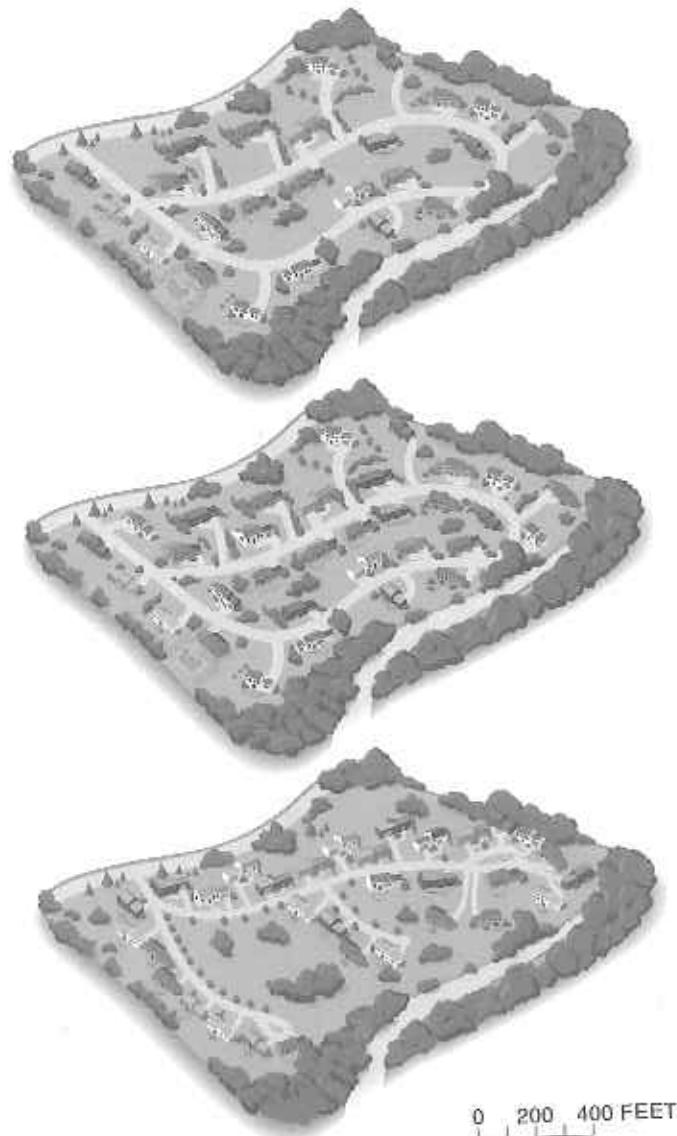

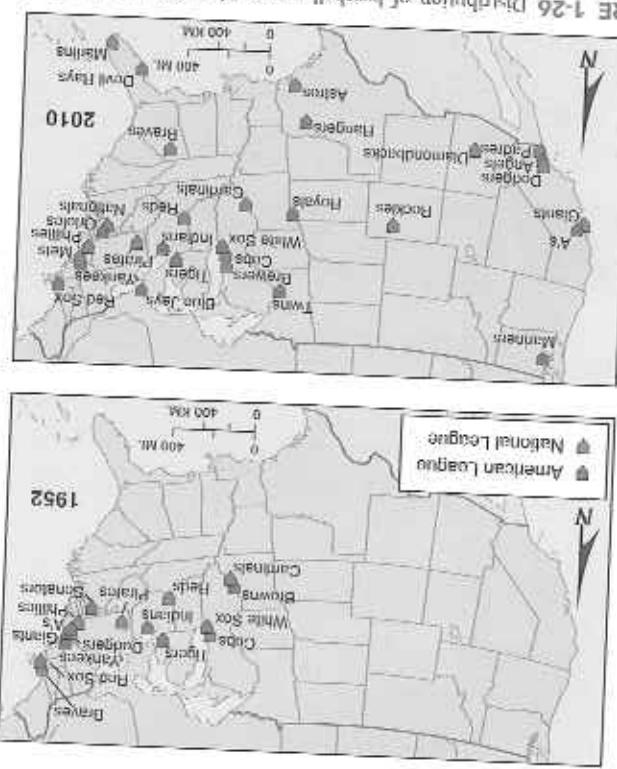

FIGURE 1-25 Distribution. The top plan for a residential area has a lower density than the middle plan (24 houses compared to 32 houses on the same 82-acre piece of land), but both have dispersed concentrations. The middle and lower plans have the same density (32 houses on 82 acres), but the distribution of houses is more clustered in the lower plan. The lower plan has shared open space, whereas the middle plan provides a larger, private yard surrounding each house.

DENSITY. The frequency with which something occurs in space is its **density**. The feature being measured could be people, houses, cars, volcanoes, or anything. The area could be measured in square kilometers, square miles, hectares, acres, or any other unit of area.

Arithmetic density, which is the total number of objects in an area, is commonly used to compare the distribution of population in different countries. The arithmetic density of Belgium, for example, is 345 persons per square kilometer (900 persons per square mile). This density is the country's total population (10.5 million people) divided by its area (30,278 square kilometers, or 11,690 square miles).

Remember that a large population does not necessarily lead to a high density. Arithmetic density involves two measures—the

FIGURE 1-26 Distribution of basketball teams. North American basketball teams illustrate the difference between density and concentration.

CONCENTRATION. If the extent of a feature's spread over space is its concentration. If the objects in an area are close together, they are clustered; if relatively far apart, they are dispersed. To compare the level of concentration most directly, two areas need to have the same number of objects and the same size area.

Geographers measure density in other ways, depending on the subject being studied. A high **physiological density**—the number of persons per unit of area suitable for agriculture—may mean that a country has difficulty growing enough food to support its population. A high **agricultural density**—the number of farmers per unit area of farmland—may mean that a county has inefficient agriculture (see Chapter 2). A high housing density—the number of dwellings units per unit of area—may mean that people live in overcrowded housing.

High population density is also unrelated to poverty. The Netherlands, one of the world's wealthiest countries, has an arithmetic density of 398 persons per square kilometer (1,031 persons per square mile). One of the poorest countries, Mali, has an arithmetic density of only 10 persons per square kilometer (26 persons per square mile).

In the world, China, with approximately 1.3 billion inhabitants, has 123 times more inhabitants than Belgium, it has more than 300 times more land by no means has the highest density. The arithmetic density of China—139 persons per square kilometer (360 persons per square mile)—is less than half that of Belgium. Although China has 123 times more inhabitants than Belgium, it has more than 300 times more land.

Number of people and the land area. The most populous country in the world, China, with approximately 1.3 billion inhabitants,

systems of lowrithms, ranges, and sections established by the pattern. Many American cities contain a square or rectangular pattern, known as a grid pattern, whereas others are distributed irregularly arranged in a square or rectangular pattern.

Objects are frequently arranged along a street or streets, such as the arrangement of houses along a linear distribution, such as the arrangement of buildings in a geometric pattern (Figure 1-27). Geographers observe that many objects form a linear distribution, such as the arrangement of streets, known as a grid pattern, which intersects at right angles to the street.

As a result of these locations and addititons, the density of roads increased, and the distribution became more dispersed.

* Indians—Cleveland to Boston in 1961, then to Boston in 1965

* Twins—Minneapolis in 1968

PATTERN. The third property of distribution is **Pattern**, which is the geometric arrangement of objects in space. Some

occupy by the expansion teams, resulting in a more dispersed pattern. The moves of the West Coast and Southwest, as well as the spaces in the Northeast and Midwest, resulted in a more concentrated pattern.

FIGURE 1-27 Pattern. Much of the farmland in the United States, including in Eastern Washington State, forms a checkerboard pattern. The pattern is a result of the township and range system (see Figure 1-5).

Land Ordinance of 1785 is another example of a square or grid pattern.

A sinister pattern of two dozen pipe bombs was placed on the American landscape in 2002 by Lucas Helder, a University of Wisconsin-Stout art student. The bomber confessed that he was trying to create a large "smile" pattern across the U.S. interior. He got as far as creating the two "eyes" by placing bombs in two large circles, one in Nebraska and one in eastern Iowa and western Illinois. Before being caught, he also placed bombs in Colorado and Texas to start the "mouth."

Gender and Ethnic Diversity in Space

Patterns in space vary according to gender and ethnicity. Consider first the daily patterns of an "all-American" family of mother, father, son, and daughter. Leave aside for the moment

that this type of family constitutes less than one-fourth of American households.

In the morning Dad gets in his car and drives from home to work, where he parks the car and spends the day; then, in the late afternoon, he collects the car and drives home. The location of the home was selected in part to ease Dad's daily commute to work.

The mother's local-scale travel patterns are likely to be far more complex than the father's. Mom takes the children to school and returns home. She also drives to the supermarket, visits Grandmother, and walks the dog. In between she organizes the several thousand square feet of space that the family calls home. In the afternoon, she picks up the youngsters at school and takes them to Little League or ballet lessons. Later, she brings them home, just in time for her to resume her responsibility for organizing the home.

Most American women are now employed at work outside the home, adding a substantial complication to an already complex pattern of moving across urban space. Where is her job located? The family house was already selected largely for access to Dad's place of employment, so Mom may need to travel across town. Who leaves work early to drive a child to a doctor's office? Who takes a day off work when a child is at home sick?

The importance of gender in space is learned as a child. Which child—the boy or girl—went to Little League and which went to ballet lessons? To which activity is substantially more land allocated in a city—ballfields or dance studios?

If the family described above consisted of persons of color, its connections with space would change. The effects of race on spatial interaction can be seen across America. In downtown Dayton, Ohio, for example, watch the people at the bus stops along the main east-west street, Third Street. In the afternoon, when office workers are heading home, persons of color are waiting on the north side of Third Street for westbound buses, while whites are waiting on the south side for eastbound buses. Why do persons of color head west on Dayton's afternoon buses? Virtually all African Americans in Dayton live on the west side, whereas the east side is home to a virtually all-white population. In most U.S. neighborhoods, the residents are virtually all white people or virtually all persons of color.

Although it is illegal to discriminate against people of color, segregation persists in part because people want to reinforce their cultural identity by living near persons of similar background and in part because persons of color have lower-than-average incomes. But many Americans of European ancestry still practice discrimination because of a deep-seated fear of spatial interaction with a person of color.

Openly homosexual men and lesbian women may be attracted to some locations to reinforce spatial interaction with other gays. San Francisco reinforces its reputation as a sympathetic home for homosexuals and lesbians through inclusive public policies (Figure 1-28). Specific neighborhoods in other cities are known to have large gay populations.

A pet dog doesn't care if you are male or female, black or white, gay or not. As long as you feed it, take care of it, and maintain close spatial interaction with it, your dog will respond with

Cultural identity is a source of pride to people at the local scale and an inspiration for personal values. Even more important than self-identification, these traits matter to older people. They are the criteria by which other people choose to interact with us. Whatever biological basis may or may not exist for disliking someone, it is important to remember that it is genetic, race, and sexual orientation that in explain why they sort the landscape in distinctive ways.

All academic disciplines and work-places have problematic sensitivity to issues of cultural diversity. For geogra- phers, concern for cultural diversity is not merely a politically correct expedi- ency; it lies at the heart of geography's spatial tradition. Nor is geography merely a matter of political correctness; it lies at the heart of geography's explanation of why each place on Earth is unique.

Geographers apply the term **space-time compression** to describe the reduction in the time it takes for something to reach another place. Distance places seem less remote and more accessible to us. We know more about what is happening elsewhere in the world, and we know sooner. Space-time compression promotes rapid change, as the culture and economy of one place reach others faster, but in time.

Places and regions. More rapid connections have reduced the distance across space between places, not literally in miles, of course, but in time.

Places

Connections Between

Airplane in about a quarter-hour and tripled the globe three times in 5 hours. At least 80 hours of sea, but in an average and sailing 37 days (nearly 900 hours) to sail across the Atlantic Ocean from the Canary Islands to San Salvador Island. In 1912, the *Titanic* was scheduled to sail from New York to Britain in about 3 days, although two-thirds of the way across, after 80 hours at sea, it hit an iceberg and sank. In 1927, Charles Lindbergh was the first person to fly nonstop across the Atlantic, taking 33.5 hours to go from Paris to New York in about 3 hours, although twice the time it took to sail from New York to Paris. In 1962, John Glenn, the first American to orbit in space, crossed above the equator in about a quarter-hour and tripled the globe three times in 5 hours.

FIGURE 1-29 Space-time compression. Transportsation improvements have

FIGURE 1-28 Diversity in space. Supporters and opponents of same-sex marriage in San Francisco watch a year earlier during a same-sex marriage in the state.

Spatial Interaction

In the past, most forms of interaction among cultural groups required the physical movement of settlers, explorers, and plunderers from one location to another. As recently as A.D. 1800, people traveled in the same ways and at about the same speeds, as in 1800 B.C.—they were carried by an animal, took a sailboat, or walked.

Today, travel by motor vehicle or airplane is much quicker. But we do not even need to travel to know about another place. We can transmit images and messages from one part of the world to another at the touch of a button. We can communicate instantly with people in distant places through computers and telecommunications, and we can instantly see people in distant places on television. The various forms of communication have made it possible for people in different places to be aware of the same cultural beliefs, forms, and traits. When places are connected to each other through a network, geographers say there is spatial interaction between them. Interaction takes place through networks, which are chains of communication that connect places. A well-known example of a network in the United States is the television network (ABC, CBS, FOX, NBC, PBS). Each comprises a chain of stations around the country simultaneously broadcasting the same program, such as a football game.

Transportation systems also form networks that connect places to each other. Airlines in the United States, for example, have adopted distinctive networks known as "hub-and-spokes" (Figure 1-30). Under the hub-and-spokes system, airlines fly planes from a large number of places into one hub airport within a short period of time and then a short time later send the planes to another set of places. In principle, travelers originating in relatively small towns can reach a wide variety of destinations by changing planes at the hub airport.

Interaction among groups can be retarded by barriers. These can be physical, such as oceans and deserts, or cultural, such as language and traditions. We regard the landscape as part of our inheritance from the past. As a result, we may be reluctant to modify it unless we are under heavy pressure to do so. A major change in the landscape may reflect an upheaval in a people's culture. Typically, the farther away one group is from another, the less likely the two groups are to interact. Contact diminishes with increasing distance and eventually disappears. This trailing-off phenomenon is called **distance decay**. Electronic communications, such as text messaging and e-mail, have removed barriers to interaction between people who are far from each other. The birth of these electronic communications was once viewed as the "death" of geography, because they made it cheap and easy to stay in touch with someone on the other side of the planet. Regardless of its location, a business could maintain instantaneous communications among employees and with customers.

In reality, geography matters even more than before. Internet access depends upon availability of electricity to power the computer and a service provider. Broadband service requires proximity to a digital subscriber line (DSL) or cable line. The Internet has also magnified the importance of geography, because when an individual is online, the specific place in the world where the individual is located is known. This knowledge is valuable information for businesses that target advertisements and products to specific tastes and preferences of particular places (see Chapter 12).

Diffusion

Diffusion is the process by which a characteristic spreads across space from one place to another over time. Today, ideas that originate in one area diffuse rapidly to other areas through sophisticated communications and transportation networks. As a result of diffusion, interaction in the contemporary world is complex. People in more than one region may improve and modify an idea at the same time but in different ways.

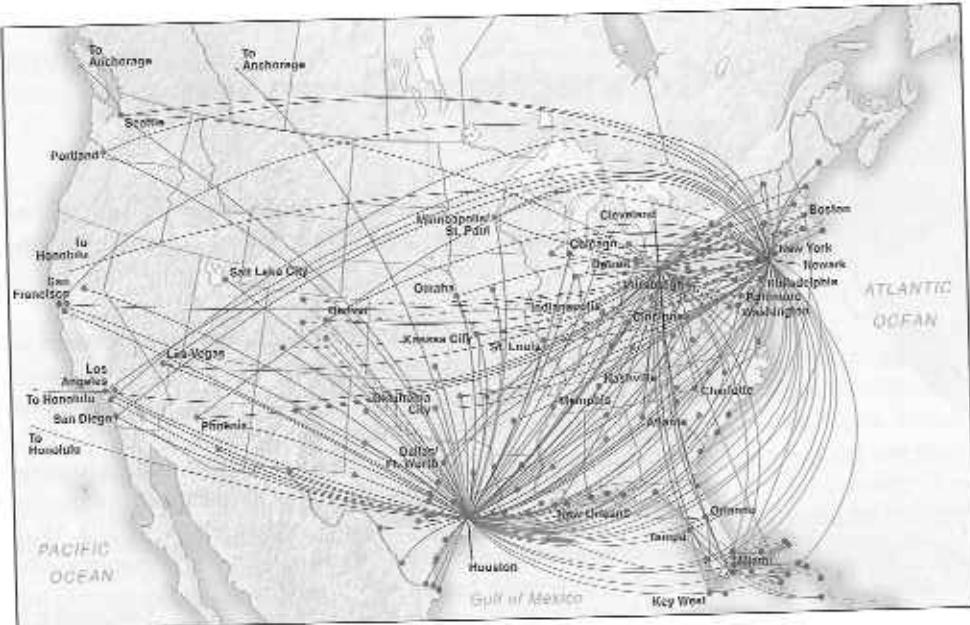

FIGURE 1-30 Continental Airlines' network. Continental, like other major U.S. airlines, has configured its route network in a system known as "hub and spokes." Lines connect each airport to the city to which it sends the most nonstop flights. Most flights originate or end at one of the company's hubs, especially at Houston, Newark, and Cleveland.

The place from which an innovation originates is called a **hearth**. Something originates at a hearth or node and diffuses from there to other places. Geographers document the location of nodes and the processes by which diffusion carries things elsewhere over time. How does a hearth emerge? A cultural group must be willing to try something new and be able to allocate resources to nurture the innovation. To develop a hearth, a group of people must also have the technical ability to achieve the desired idea and the economic structures, such as financial institutions, to facilitate implementation of the innovation.

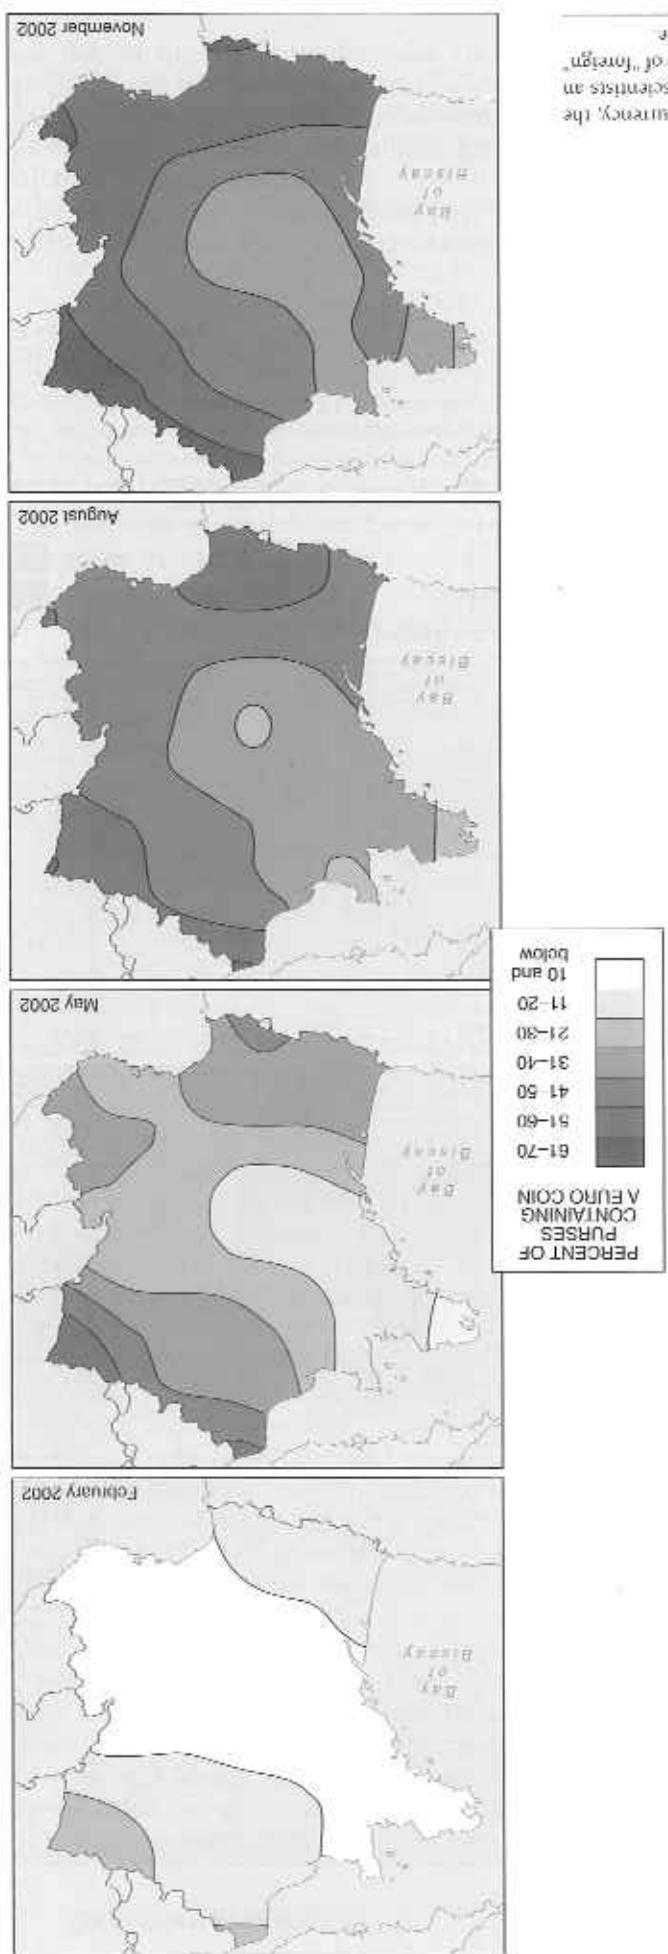

FIGURE 1-37 Belief on disillusion. In addition to a column of percentages, the figure includes a caption: "In 17 Western European countries in January 2002, 52% of scientists believe that there is a measure of the level of inflation distortion into France which opportunity to measure telecommunication diffusion. The percentage of 'foreign' who comes to a measure of the level of inflation distortion into France."

Geographic distribution helps us understand the distribution of acquired immunodeficiency syndrome (AIDS) within the United States. New York, California, and Florida were the modes of origin for the disease within the United States during the early 1980s (Figure 1-32). Half of the 50 states had no reported cases, whereas New York City, with only 3 percent of the nation's population, counted more than one-fourth of the AIDS cases. New AIDS cases differed in every state during the 1980s and early 1990s, although California, Florida, and New York remained the leaders. These three states, plus Texas, accounted for half of the nation's new AIDS cases in the peak year of 1993. At a national scale, the

In introduction of a common currency, the euro, in 12 West-European countries gave scientists an unusual opportunity to measure relocation diffusion from heralds (Figure 1-31). Although a single set of paper money was issued, each country had its own costs in proportion to its share of the regional economy. A country's coins were usually distributed only inside its borders, although the coins could also be used in the other 11 countries. Scientists took month-long mouth samples in France to monitor the proportion of coins from each of the other 11 countries. The percentage of coins from a particular country is a measure of the level of relocation diffusion to and from France.

The most commonly spoken languages in North and South America are Spanish, English, French, and Portuguese, primarily because several hundred years ago Europeans who spoke those languages compassed the largest number of migrants. Thus these languages spread like the diffusion of religion. We will examine the diffusion of languages, religions, and ethnicity.

RELIGION DIFFUSION. The spread of an idea through physical movement of people from one place to another is termed **religion diffusion**. We shall see in Chapter 3 that people migrate for a variety of political, economic, and environmental reasons. When they move, they carry with them their culture, language, religion, and ethnicity.

RELOCATION DIFFUSION. The spread of an idea through

For a person, object, or idea to have interaction with persons, objects, or ideas in other regions, diffusion must occur—recognition, or basic types of diffusion— relocation and expansion.

As discussed in subsequent chapters, geographers can trace the dominant cultural, political, and economic features of the continentally important United States and Canada primarily to heredities in Europe and the Middle East. Other regions of the world also contain important heritages. In some cases, such as an agricultural practice, may originate independently in more than one part of the earth. In other cases, heritages may emerge in two regions because two cultural groups modify a shared concept in two different ways.

FIGURE 1-32 Diffusion of AIDS in the United States. Acquired immunodeficiency syndrome (AIDS) diffused across the United States from nodes in New York, California, and Florida. In 1981, virtually all people with AIDS were found in these three nodes. During the 1980s, the number of cases increased everywhere, but the incidence remained highest in the three original nodes. The number of cases declined relatively rapidly in the original nodes during the 1990s. The AIDS Memorial Quilt, on display in Washington, DC, was assembled as a memorial to people who died of AIDS.

diffusion of AIDS in the United States through relocation diffusion halted after 1993. The number of new AIDS cases dropped by one-fourth in just two years.

Relocation diffusion can explain the rapid rise in the number of AIDS cases in the United States during the 1980s and early 1990s, but not the rapid decline beginning in the mid-1990s. Instead, the decline resulted from the rapid diffusion of

preventive methods and medicines such as AZT. The rapid spread of these innovations is an example of expansion diffusion rather than relocation diffusion.

EXPANSION DIFFUSION. The spread of a feature from one place to another in a snowballing process is **expansion diffusion**. This expansion may result from one of three processes:

capital from nodes of origin to other regions. Every area of the world plays some role in transnational trade. In the past were largely unaffected by events elsewhere in the world now share a single economic and cultural world with other workers and cultural groups. The fate of an autoworker in Detroit is tied to investment decisions made in Mexico City, Seoul, Stuttgart, and Tokyo.

Innovations may also originate in a particular node or place of power, such as a large urban center, and diffuse later to isolated rural areas. Lip-to-lip from socially elite people, but it originated in urban areas. Contagious diffusion is the rapid, widespread diffusion of a characteristic throughout the population. As the term implies, this form of diffusion is analogous to the spread of a contagious disease, such as influenza. Contagious diffusion spreads like a wave among fans in a stadium, without regard for hierarchy and without requiring permanent relocation of people. The rapid adoption throughout the United States of AIDS prevention methods and new medicines is an example of contagious diffusion. An idea placed on the World Wide Web spreads through contagious diffusion, because Web surfers throughout the world have access to the same material simultaneously — and quickly.

Contagious diffusion is the rapid, widespread diffusion of a characteristic throughout the population. As the term implies, this form of diffusion is analogous to the spread of a contagious disease, such as influenza. Contagious diffusion spreads like a wave among fans in a stadium, without regard for hierarchy and without requiring permanent relocation of people. The rapid adoption throughout the United States of AIDS prevention methods and new medicines is an example of contagious diffusion. An idea placed on the World Wide Web spreads through contagious diffusion, because Web surfers throughout the world have access to the same material simultaneously — and quickly.

Hierarchical diffusion is the spread of an idea from persons or nodes of authority or power to other persons or places. Hierarchical diffusion may result from the spread of ideas from political leaders, socially elite people, or other important persons or nodes of authority or power to other persons or places. Sons or daughters of influential leaders, such as Bill Gates, may result from the spread of ideas from the World Wide Web. Even if the physical distance between two places — as measured in kilometers or miles — is large,

SUMMARY

Each chapter has a summary that reviews the chapter's most important concepts. The summary is organized around the major headings within the chapter.

In all of the subsequent chapters, these headings will be in the form of questions that are answered in the text. In this first chapter, the principal headings concern thinking about five key concepts in geography (place, region, scale, space, and connections):

1. How Do Geographers Describe Where Things Are?

Geography is most fundamentally a spatial science. Geographers use maps to display the location of objects and to extract information about places. Early geographers drew maps of Earth's surface based on exploration and observation. GIS and other contemporary tools assist geographers in understanding reasons for observed regularities across Earth.

2. Why Is Each Point on Earth Unique? Every place in the world has a unique location or position on Earth's surface. Geographers also identify regions as areas distinguished by distinctive combinations of cultural as well as economic and environmental features. The distributions of features help us to understand why every place and every region is unique.

3. Why Are Different Places Similar? Geographers work at all scales, from local to global. The global scale is increasingly important because few places in the contemporary world are totally isolated. Because places are connected to each other, they display similarities. Geographers study the interactions of groups of people and human activities across space, and they identify processes by which people and ideas diffuse from one location to another over time.

CASE STUDY REVISITED / The Geography of a Big Mac Attack

Geography in the News

Each chapter in this book concludes by reviewing the opening case study in light of the issues raised in the chapter. This chapter presents five basic concepts—place, region, scale, space, and connections. The opening case study offers a typical everyday geographic concern—a search for a restaurant—to which these five concepts can be applied.

Geography is fundamentally concerned with the organization of space. McDonald's restaurants are not distributed randomly across the landscape; rather, each restaurant has a unique location that can be depicted on a map (Figure 1-33).

Geographers use maps to describe where these establishments are found and explain why they are so arranged. Because "where" and "why" are the questions most fundamental to geographic inquiry, they are used to organize the material presented within all of the other chapters in this book.

Geographers observe from a map that McDonald's restaurants cluster in some regions, whereas other regions have few. A world map of McDonald's restaurants helps us to understand global-scale patterns of investment by a major international corporation. Most McDonald's are located in countries where average incomes are high enough to buy the products.

A world map of McDonald's doesn't help a hungry American driving on an interstate highway. The motorist needs a local-scale map showing the location of McDonald's in relation to specific highway exit ramps. As McDonald's have diffused from the United States to other regions of the world, each McDonald's is connected to all other McDonald's by a communications network through which uniform standards and practices are set.

FIGURE 1-33 Fast food nation. Franchised restaurants cluster near each other, such as along Highway 412 in Springdale, Arkansas.

In subsequent chapters, these five basic concepts will be applied to elements of human geography:

- Chapters 2 and 3 where humans are clustered in the world, why the number of people has increased in some places, and why people have moved to certain places

(Continued)

CASE STUDY REVIEWED (Continued)

- Chapters 9 through 14 where different economic activities are found around the world, why people earn a living in different ways in different regions of the world, and why people increase, injury earn a living by residing in urban areas.

KEY TERMS

- | | | | | | | | | | |
|--|--|--|--|--|---|--|---|---|--|
| Agricultural density (p. 33) The ratio of the number of farmers to the total amount of land suitable for agriculture. | Population density (p. 9) A law that divided much of the United States into territories. | Latitude (p. 15) The number of parallels drawn on a globe and measuring distance north and south of the equator (0°). | Longitude (p. 15) The number of meridians used to indicate the location of anything on Earth's surface. | Map (p. 4) A two-dimensional, or flat, representation of Earth's surface or a portion of it. | Mental map (p. 20) A representation of a portion of Earth's surface based on what individual knows about a place. | Meridian (p. 15) A circle drawn on a map between the North and South poles. | Parallel (p. 15) A circle drawn around the globe parallel to the equator and at right angles to the meridians. | Pattern (p. 33) The geometric or regular arrangement of something in a study area. | Physical sciences , Geography was therefore the study of how the physical environment caused human activities. |
| Amicticultural density (p. 33) The ratio of the number of farmers to the total amount of land suitable for agriculture. | Base line (p. 9) An east-west line designated under the Land Ordinance of 1785 to facilitate the surveying and numbering of townships in the United States. | Formal region (or uniform or homogeneous region) (p. 17) An area in which everyone shares in one or more distinctive characteristics. | Functional region (or nodal region) (p. 19) An area organized around a node or focal point. | Geographic information system (GIS) (p. 12) A computer system that stores, organizes, analyzes, and displays geographic data. | Global Positioning System (GPS) (p. 9) A system that determines the precise position of something on Earth through a series of satellites, tracking a node or focal point. | Globahization (p. 29) Actions of individuals, societies of satellites, tracking and revealing in making something worldwide in scope. | Greenwich Mean Time (GMT) (p. 18) The time in the zone encompassing the prime meridian, or 0° longitude. | Hearth (p. 36) The region from which innovations spread. | Humanitarianism (p. 36) The diminishing in importance of territory over time. |
| Amicticultural distribution (p. 32) The arrangement of people per unit of arable land. | Homogeneous region (p. 17) An area in which everyone shares in one or more distinctive characteristics. | Informal region (or nodal region) (p. 19) An area organized around a node or focal point. | Interregional Date Line (p. 18) A line across Earth's surface that follows 180° longitude, although it deviates in several places to avoid dividing land areas. When you go west (toward Asia), the calendar moves ahead one day. | Land Ordinance of 1785 (p. 9) A law that divided much of the United States into territories. | Latitude (p. 15) The number of parallels drawn on a globe and measuring distance north and south of the equator (0°). | Longitude (p. 15) The number of meridians used to indicate the location of anything on Earth's surface. | Meridian (p. 15) A circle drawn around the globe parallel to the equator and at right angles to the meridians. | Pattern (p. 33) The geometric or regular arrangement of something in a study area. | Population density (p. 32) The arrangement of people per unit of area. |
| Amicticultural distribution (p. 32) The arrangement of people per unit of area. | Homogeneous region (p. 17) An area in which everyone shares in one or more distinctive characteristics. | Informal region (or nodal region) (p. 19) An area organized around a node or focal point. | Interregional Date Line (p. 18) A line across Earth's surface that follows 180° longitude, although it deviates in several places to avoid dividing land areas. When you go west (toward Asia), the calendar moves ahead one day. | Land Ordinance of 1785 (p. 9) A law that divided much of the United States into territories. | Latitude (p. 15) The number of parallels drawn on a globe and measuring distance north and south of the equator (0°). | Longitude (p. 15) The number of meridians used to indicate the location of anything on Earth's surface. | Meridian (p. 15) A circle drawn on a map between the North and South poles. | Pattern (p. 33) The geometric or regular arrangement of something in a study area. | Population density (p. 32) The arrangement of people per unit of area. |

Possibilism (p. 24) The theory that the physical environment may set limits on human actions, but people have the ability to adjust to the physical environment and choose a course of action from many alternatives.

Prime meridian (p. 15) The meridian, designated as 0° longitude, that passes through the Royal Observatory at Greenwich, England.

Principal meridian (p. 9) A north-south line designated in the Land Ordinance of 1785 to facilitate the surveying and numbering of townships in the United States.

Projection (p. 8) The system used to transfer locations from Earth's surface to a flat map.

Region (p. 5) An area distinguished by a unique combination of trends or features.

Regional (or cultural landscape) studies (p. 17) An approach to geography that emphasizes the relationships among social and physical phenomena in a particular study area.

Relocation diffusion (p. 37) The spread of a feature or trend through bodily

movement of people from one place to another.

Remote sensing (p. 9) The acquisition of data about Earth's surface from a satellite orbiting the planet or from other long-distance methods.

Resource (p. 24) A substance in the environment that is useful to people, is economically and technologically feasible to access, and is socially acceptable to use.

Scale (p. 5) Generally, the relationship between the portion of Earth being studied and Earth as a whole; specifically, the relationship between the size of an object on a map and the size of the actual feature on Earth's surface.

Section (p. 9) A square normally 1 mile on a side. The Land Ordinance of 1785 divided townships in the United States into 36 sections.

Site (p. 14) The physical character of a place.

Situation (p. 14) The location of a place relative to another place.

Space (p. 5) The physical gap or interval between two objects.

Space-time compression (p. 35) The reduction in the time it takes to diffuse something to a distant place as a result of improved communications and transportation systems.

Stimulus diffusion (p. 39) The spread of an underlying principle, even though a specific characteristic is rejected.

Toponym (p. 13) The name given to a portion of Earth's surface.

Township (p. 9) A square normally 6 miles on a side. The Land Ordinance of 1785 divided much of the United States into a series of townships.

Transnational corporation (p. 30) A company that conducts research, operates factories, and sells products in many countries, not just where its headquarters or shareholders are located.

Uneven development (p. 39) The increasing gap in economic conditions between core and peripheral regions as a result of the globalization of the economy.

Vernacular region (or perceptual

region) (p. 19) An area that people believe exists as part of their cultural identity.

THINKING GEOGRAPHICALLY

1. Cartography is not simply a technical exercise in penmanship and coloring, nor are decisions confined to scale and projection. Mapping is a politically sensitive undertaking. Look at how maps in this book distinguish between the territories of Israel and its neighbors and the locations of borders in South Asia, the Arabian Peninsula, and northwest Africa. Are there other logical ways to draw boundaries and distinguish among territories in these regions? What might they be?
2. Imagine that a transportation device (perhaps the one in Star Trek or Harry Potter) would enable all humans to travel instantaneously to any location on Earth's surface. What would be the impact of that invention on the distribution of peoples and activities across Earth?
3. When earthquakes, hurricanes, or other environmental disasters strike, humans tend to "blame" nature and see themselves as the innocent victims of a harsh and cruel nature. To what extent do environmental hazards stem from unpredictable nature and to what extent do they originate from human actions? Should victims blame nature, other humans, or themselves for the disaster? Why?
4. The construction of dams is a particularly prominent example of human-environment interaction in regions throughout the world. Turkey built the Ataturk Dam on the Euphrates River, a move opposed by Syria and Iraq, the two downstream countries. Similarly, the Belo Monte Dam on the Xingu River, a tributary of the Amazon, generated considerable opposition in Brazil. Some Russians oppose construction of the St. Petersburg Dam in the Gulf of Finland. Egypt, which operates the Aswan Dam on the Nile River, has blocked loans to Ethiopia that could be used to divert the source of the Nile. Why do governments push the construction of dams so forcefully, and why do others oppose their construction so passionately?
5. Geographic concepts are supposed to help explain contemporary issues. Are there any stories in your newspaper to which geographic concepts can be applied to help understand the issues? Discuss.
